Case 2 had symptoms of gastric retention in the immediate postoperative period This was clearly demonstrated by barium meal even of the ordinary type After three years he developed gastric ulcer, which was shown radiologically It was thought that his increasing pain was probably due to this, but in the interval, while awaiting admission, he had jaundice, which necessitated a further laparotomy, at which it was found that he had inoperable carcinoma of the head of the pancreas Owing to adhesions round the anastomosis it was difficult to ascertain whether there was any ulcer in the stomach Cholecystenterotomy was performed and the patient is now recovering from this operation

Mortality

The one postoperative death took place six years ago It happened before the full significance of potassium deficiency was recognised The patient had postoperative gastric retention which did not respond to the usual measures He died on the eighteenth postoperative day Necropsy did not reveal any technical failure but showed that he had lower-nephron nephrosis Such a fatal set of circumstances is unlikely to recur This single death gives a mortality of 0 5% in this series

Comment

The series is presented at this stage because I feel that the results to date of the standardised procedure of vagotomy combined with large stoma, drainage, and posterior gastrojejunostomy are encouraging This operation satisfies the requirements laid down by Oberhelman and Dragstedt (1955) If the principles of this operation are correct, and duodenal ulcer is due to the unbuffered action of gastric secretion, the probability is that, provided the operation is properly done, the results should be permanent The passage of time appears to show no deterioration in the proportion of satisfactory results (fig 2)

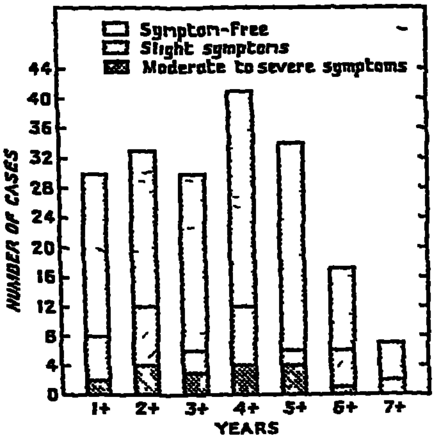

Fig 2—The vertical columns represent the number of operations per year The passage of time shows no deterioration in the proportions of satisfactory results

This series supports the view expressed by Lloyd Davies, reviewing the five year results of many British surgeons, that poor results of vagotomy and gastro jejunostomy tend to declare themselves early (Davies 1956) The better figures in the present series may well be due to the use of a standardised procedure in which the primary objective of the gastrojejunostomy has been drainage

The results of a few operations consisting of vagotomy and pyloroplasty for duodenal ulcer (not included in the present review) support the opinion of Lloyd Davies that this combination is not so satisfactory as that of vagotomy and gastrojejunostomy, the drainage is less adequate, and therefore the improvement produced by this operation is unlikely to be so permanent It is also undesirable to interfere with the duodenum in the presence of an active duodenal ulcer, and one of the great advantages of vagotomy and gastrojejunostomy is that the duodenum is left in situ and intact This is undoubtedly one of the main reasons why a lower mortality is to be expected from this operation

It is true that gastrojejunostomy alone may cure some cases, especially in the older age-groups Probably, in cases where this treatment proves satisfactory, the factors originally responsible for the ulcer have ceased to operate, through the passage of years or through changing circumstances By-passing a chronic ulcer would then prove efficient

It is not easy, however, to estimate how completely the patient's habits and mode of life have changed since the onset of symptoms The addition of vagotomy to gastrojejunostomy does little to increase the risk of the operation and deals permanently with the disordered physiology thought to be so important in these cases

The treatment of combined duodenal and gastric ulcer although infrequent, has been by gastrectomy, and I agree with Johnson (1956) that in these cases the gastric ulcer results from gastric retention In 1 case in this series, where a high gastric ulcer was associated with a duodenal ulcer, treatment was by vagotomy and gastro-enterostomy because removal of the ulcer would have meant almost total gastrectomy This patient has remained symptom free for more than three years

Summary

The results of vagotomy and gastrojejunostomy in 197 cases of duodenal ulcer are reported The patients were operated on by a standardised technique in a period of eight years

This review supports the opinion of Oberhelman and Dragstedt (1955) that, provided vagotomy is complete and drainage adequate the results will compare favourably with any other operation so far devised to treat duodenal ulcer

I acknowledge with gratitude the help of my secretaries, Miss D Brown and Mrs E Short, of Miss J Daniels for her diagrams, and of the house surgeons and nurses of wards 19 and 20 who have cared for these patients after operation.

"   We do not know how to postpone our inevitable dissolution beyond our allotted span, but, by prolonging our flowing years, we may perhaps shorten our ebb of life There is too much talked today of rehabilitation, too little attention paid to habilitation, by which we mean enabling people still to continue in their daily lives without faltering by the wayside   The geriatricians, though they may have rescued many an old person from a paradise of bedfastness and placed them in a state of uncertain mobility, are not interested in the acuter illnesses of those on the verge of old age, and we are concerned that the very existence of this specialty should have created an artificial division between those in middle life and those who are past their prime There is much to be said for the system which *admits all* sick to one general hospital and will not allow the admission of old people directly to geriatric units   Acute infections these days, are as rapidly cured in the old as in the young, though recovery may be slower, there is however no reason why on that account the elderly should be denied their rightful place in a general hospital when they go down with acute illness"—Editorial in the *College of General Practitioners' Research Newsletter*, May, 1957 p 96

MALIGNANT GROWTH IN THE LIVER AND SERUM-VITAMIN-B_{12} LEVELS *

High serum-vitamin-B_{12} levels have been found in acute liver disease (Rachmilewitz et al 1955, 1956) and occasionally in cirrhosis of the liver In acute hepatitis the serum-vitamin-B_{12} level rose in the acute phase of the disease, when disintegration of liver-cells was most pronounced It was therefore assumed that the injured liver cells released into the blood stream the vitamin B_{12} stored in the liver This assumption was supported by findings in dogs with acute liver necrosis induced by carbon tetrachloride Extremely high serum-vitamin-B_{12} levels (up to fourteen times as high as the normal level) were found in these dogs as early as 1–2 hours after the intraportal administration of carbon tetrachloride (Stein et al 1956)

The interrelationship between liver damage and a raised serum-vitamin-B_{12} level prompted us to estimate the serum-vitamin B_{12} levels of patients with neoplastic disease involving the liver

Methods

Vitamin B_{12} was determined microbiologically with the aid of a mutant strain of *Escherichia coli* as described previously (Grossowicz et al 1954, Rachmilewitz et al 1956) Only the total serum-vitamin-B_{12} was determined This was done in either of the following two ways (1) by diluting the serum 1 8 with distilled water, heating for 30 minutes at 100°C, and adding the heated mixture aseptically to the medium , or (2) by liberating the vitamin B_{12} from the serum-proteins by acid precipitation (0 6% acetate buffer , pH 4 6), autoclaving for 30 minutes at a pressure of 10 lb in the presence of cyanide (0 2 mg per ml of undiluted serum), and assaying the neutralised supernatant fluid

The serum-vitamin-B_{12} values of 35 healthy people ranged from 200 to 500 (mean 340) µµg per ml

Results

18 patients with various malignant tumours extensively involving the liver were investigated The malignancy and the hepatic metastases were diagnosed on the basis of clinical findings, biopsy at laparotomy, or necropsy findings In most of these patients the liver was heavily infiltrated with tumour tissue Mild to moderate jaundice was an accompanying sign in 8 patients In 16 of 18 patients the serum vitamin B_{12} level was found to be raised (640–20,000 µµg per ml) (see table) In cases 8 and 9 with malignant melanoma involving the liver the serum vitamin-B_{12} level was moderately raised (800 and 820 µµg per ml) In case 10, however, with a like tumour, the serum vitamin B_{12} level was excessively high (5800 µµg per ml)

The highest serum-vitamin B_{12} level (20,000 µµg per ml) was found in case 2, who had undergone total gastrectomy for cancer of the stomach When the level was estimated several months after the gastrectomy, the liver was extensively infiltrated with metastases causing jaundice

In case 16, with multiple myeloma, necropsy showed extensive amyloidosis of the liver causing flattening and displacement of the liver-cells by amyloid, and the serum vitamin-B_{12} level was raised at several examinations In 2 patients with multiple myeloma not complicated by amyloid the serum-vitamin-B_{12} level was normal

In case 15, a girl aged 19 with cancer of the ovary, the liver was heavily infiltrated with metastases, and

histological examination revealed atrophy of the liver-cells adjacent to the tumour Her serum-vitamin-B_{12} level was 4800 μμg per ml

In case 12, with hepatoma in a cirrhotic liver and a raised serum-vitamin-B_{12} level (4350 μμg per ml), the entire liver was found at necropsy to be infiltrated with tumour tissue, but in case 11, with hepatoma and a normal serum-vitamin-B_{12} level (470 μμg per ml), the tumour was limited to a circumscribed area, leaving the rest of the liver intact

In 19 control patients with malignant diseases involving various organs but without evidence of liver metastases the serum-vitamin-B_{12} levels were normal (100–550 μμg per ml) (see table)

Discussion

These results show that invasion of the liver by a malignant growth is accompanied by a rise in the serum-vitamin-B_{12} level The invading tumour, by causing necrosis and/or displacement of liver-cells, allows vitamin B_{12} to escape from the liver into the blood Damage of liver-cells by virus (Rachmilewitz et al 1955, 1956, Kristensen 1956) or by carbon tetrachloride (Stein et al 1956) similarly raises the serum-vitamin-B_{12} level.

In liver disease, whether of viral or of chemical origin, the serum-vitamin-B_{12} level increases rapidly but only temporarily (lasting only 1–2 weeks in hepatitis and a few days in liver injury from carbon tetrachloride) and then falls rapidly to normal levels In cancer of the liver the process damaging the liver is more prolonged , hence a persistent rise of serum-vitamin-B_{12} level is to be expected Persistent rises were actually found in 3 patients (cases 5, 14, and 16) in whom estimations of serum-vitamin-B_{12} were repeated in the course of illness (see table)

That the neoplastic process per se is not responsible for the rise of serum-vitamin-B_{12} level is shown by finding normal levels in the controls with various malignant tumours but no evidence of liver metastases These findings suggest that *determination of the serum-vitamin* B_{12} may help the diagnosis of metastases to the liver in cases of malignancy Raised levels should be interpreted as an indication that the liver is involved Normal levels, however, do not rule out this possibility, because metastasising tumours not causing liver damage could be present in the liver without raising the serum-vitamin-B_{12} level

Vitamin B_{12} is not the only substance released from liver-cells affected by tumour Wroblewski and La Due (1955) reported that the level of glutamic oxalacetic transaminase in the serum was raised in virus hepatitis, carbon-tetrachloride poisoning, and malignancy with liver metastases However, whereas increased transaminase activity of the serum is found in destruction of various tissues, including heart muscle as in myocardial infarction (Wroblewski and La Due 1955), raised serum-vitamin-B_{12} levels are found only when the injured tissue is liver

The serum-vitamin B_{12} level is also much raised in myeloid leukæmia (Beard et al 1954 Killander 1954, Mollin and Ross 1955, Rachmilewitz et al 1957) Whether a mechanism common to liver disease and myeloid leukæmia is responsible or not for the striking rise in serum-vitamin-B_{12} levels in these two conditions remains to be elucidated.

Summary

Serum-vitamin B_{12} levels were determined microbiologically in patients with malignant disease

In 19 patients without metastases in the liver the serum vitamin-B_{12} levels were normal (100–550 μμg per ml) whereas in 16 of 18 patients with metastases in the liver the levels were raised (640–20,000 μμg per ml)

These and previous findings indicate that this rise in serum-vitamin-B_{12} level is due to release of the stored vitamin from damaged liver-cells

The rise of serum-vitamin-B_{12} level may be used to help the diagnosis of metastases to the liver in cases of malignancy

CHILDREN IN HOSPITAL

G F VAUGHAN
M B Lond , M R C P , D P M
CHIEF ASSISTANT, DEPARTMENT OF PSYCHOLOGICAL MEDICINE, GUY'S HOSPITAL , CONSULTANT PSYCHIATRIST, WOOD VALE RECEPTION CENTRE

CHILDREN are usually given some kind of explanation by their parents before they go into hospital Are they then less fearful and anxious ? Mac Keith (1953) pointed out that children may have varied, bizarre, and sometimes frightening ideas about the hospital What they are told may be coloured by their parents' own anxiety about an operation, which is often based on incomplete understanding of the situation and is likely to confuse the child—the opposite to what was intended.

We assume that the nurses and doctors explain what is happening, and relieve these fears Are we justified in this assumption ? Should a simple explanation be given to children soon after they are admitted ? The following investigation was undertaken with a small group of children to discover more about their attitudes towards admission and operation, and to see whether a simple introductory explanation would result in less emotional disturbance

Method

The children were all admitted to the hospital for five days for the same operation—correction of a strabismus Those living more than twenty-five miles from Central London, and those with a history of previous operations, were not included The parents were interviewed, and the child's behaviour and personality before admission was assessed and classified under a number of headings (Cameron 1955) All the children were tested briefly by a psychologist

They were divided into two groups Group A was a consecutive series of 20 children who formed a " control"

AGE, SEX, AND INTELLECTUAL LEVELS OF THE TWO GROUPS OF 20 CHILDREN ADMITTED TO HOSPITAL FOR OPERATION

	—	Group A (control)	Group B (prepared)
Age (yr)	Mean	5 9	? 9
	Standard deviation	0 61	0 62
	Range	2 5–9 2	2 3–9 9
Sex	Girls	14	14
	Boys	6	6
I Q	Mean	107	100
	Standard deviation	1 9	19 8
	Range	71–127	60–140

group. Group B comprised 20 similar children, from the same social background, who were carefully matched with their opposite numbers in group A for the criteria shown in the accompanying table. In addition to facing the same experiences as the children in group A, these children were specially interviewed by myself on their first, third, and fifth days in hospital; they formed the "prepared" group. 12 children in group A and 13 in group B had a history of some disturbance before admission.

Evidence of disturbance after operation was derived from various sources.

(1) Disturbance in the ward was estimated from a daily record of behaviour made on a proforma by the ward sister.

(2) A week after leaving the ward, in conjunction with a clinical examination, the child's behaviour was re-assessed under the diagnostic headings described by Cameron (1955).

(3) Twenty-six weeks later this examination and inquiry was repeated.

There are well-known limitations to the validity of behaviour records for estimating anxiety and emotional disturbance in children, but the method presented here was the most suitable available. A child was designated "disturbed" when he showed disturbance in more than one major aspect of behaviour. The final assessment of whether a child should be classed as still disturbed was made by an independent person who had not observed the children.

The Ward

Each child was brought to the ward by one of the parents. The details for admission were collected, the parent then left, and the child was bathed and put to bed. This took about half an hour. The child wore hospital pyjamas. He was allowed to keep any special toy he might have brought with him. During this process he would already have passed through the care of several nurses.

Soon after his admission the ward sister came to him, and lightly bandaged his eyes for a few seconds, telling him that this was what it would be like after the operation. This brief contact should not be considered a preparatory explanation or interview, for no real opportunity was given for any discussion. The child seemed to accept it as another aspect of the bewildering process of coming to the ward.

Apart from an afternoon rest period, there was little formal discipline in the ward, and there were opportunities for play, tea-parties, and television. All types of surgical patients were nursed in the ward; one special section was occupied by a burns unit, where two or more naked, burned children were usually on view.

Next day premedication was given to the child in his bed. This was singled out from surrounding beds by having a red blanket placed over it. Parents were told that they could visit throughout the afternoon of the two days during which the child's eyes were to be bandaged, and thereafter each evening.

Preparation

Children in group B only were interviewed by myself soon after admission. This interview was unhurried and the child was encouraged to talk freely. Although it lasted only fifteen to twenty-five minutes, there did not seem to be any need for further time, and the child clearly appreciated the contact made with him.

A short while in a ward cannot help but make one appreciate that much of what is said to children (and for that matter, to parents also) is beyond their intellectual grasp, particularly if they are anxious and in strange surroundings. For this reason a few specific points were introduced into this conversation in a selected order using simple phrases which the child would be likely to understand. Questions which might increase anxiety were avoided as much as possible. The child was not suddenly asked who he was, or where he had come from; I opened the conversation by using his christian name, and then telling him that I knew about his home—the purpose of this, and indeed of the whole conversation, being to establish a close and meaningful contact with him as quickly as possible. I then told him that I was there to see that he was happy, and would look after him while he was in hospital. After this reassurance, a simple explanation was given of what was to happen. I told him when his parents were coming again (which I had found out beforehand), and how many days he would be in hospital. Questions were answered as truthfully, briefly, and simply as possible.

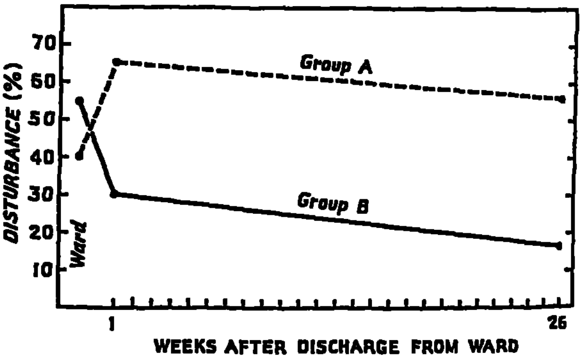

Fig. 1—Emotional disturbance in two groups of children admitted for operation.

The children were subsequently visited by me on the third and fifth days in the ward, for ten to fifteen minutes. They were encouraged to talk freely, and questions were answered.

Results

In group A, 8 children were "disturbed" in the ward and 13 at one week and 11 at twenty-six weeks after discharge. In group B the corresponding numbers were 11, 6, and 3 (fig. 1). The difference at twenty-six weeks is significant, and for this pair $\chi^2 = 5{\cdot}38$, P = just above 0·02.

When the pairs of children in each group were examined to see whether age played any part, it was evident that the children over 4 years had benefited considerably. The numbers in each group aged 4 years and more who were disturbed in the ward and at one and twenty-six weeks after discharge were respectively 7, 11, and 9 in group A (18 children), and 9, 4, and 1 in group B (18 children) (fig. 2). The difference at twenty-six weeks is significant, and for this pair $\chi^2 = 6{\cdot}7$, P = 0·01.

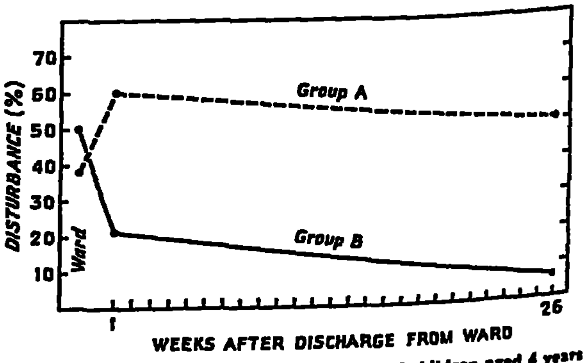

Fig. 2—Emotional disturbance in two groups of children aged 4 years or more admitted for operation.

The Children's Fears

Disturbances similar to those met with here have been fully described elsewhere (Jessner and Kaplan 1948, Prugh et al. 1953), and a detailed report would be out of place, but a few comments will illustrate the problems and responses encountered.

The parents of most of the 40 children had tried to tell them something of what to expect, but (except in 4 cases) these explanations were so incomplete, or so far from the truth, that they led to gross misconceptions in the child's mind. The parents of 9 gave no advice (4 in group A, 5 in group B). One said, "I couldn't bring myself to tell him—I was so afraid," and another, "I didn't know what to say, so I said nothing." 4 mothers told deliberate lies to avoid upsetting the children, saying they were going with them to the cinema or shopping, or going for a holiday.

A boy, aged 9 years, was trying hard to keep awake on the night of admission; his mother had told him the operation would be carried out while he was asleep. A girl, aged 8 years, refused to eat; she had been told something would be put into the food to put her to sleep for the operation.

Most children, when asked why they had come into hospital, said "for an operation," and then, asked what this was, said "don't know." A 7-year-old girl said, "I've never had an operation before in my whole life, so I can't tell you. I said to Mummy, 'Do they take your eye out?' and she said, 'No.' I said, 'Do they press your eye in?' and she said, 'No'; so I still don't know." This answer also illustrates a fear shared to some extent by all the children, fear that their eyes were to be removed, and that something important must be cut. A boy of 8 said, "They might cut it out—I don't know if they cut your eyes or not"; another of 6, "They take it out, turn it round, and cut it, and put it back"; and another, "I was one of the lucky ones, I got my own eye back."

All children over 4 were to some extent afraid of injections.

Fear was often projected on to animals or toys left at home; a pet would be said to be ill, or a favourite toy broken. As events in fantasy, these might be said to be under control, and therefore able to be brought at will to a safe and happy ending, in contrast to the uncontrolled events taking place in the ward, and in this indirect way the child was able to reassure himself about the future.

Some of the older children had repeatedly asked their parents what was to happen to them; others showed indifference or denied that they were going into hospital. In these instances their underlying anxiety appeared in other ways—general irritability, a readiness to be upset by trivialities, or temporary changes in eating and sleeping habits. Less often there was suppression and inhibition of previously disturbed behaviour. A girl, aged 7 years, on learning that she was to be admitted to hospital, became obedient, unusually quiet, and went out of her way to make sure her parents were pleased with her. We saw this reaction in 4 children in the ward, where they were clearly anxious to please as a cover for underlying insecurity, and some children reacted similarly on returning home.

There was sometimes a sudden flood of tears when the child realised what was to be talked about in the preparatory interview, or he would make comments on the ward, or reiterate a question such as "How long will I be here?" and then seem not to listen for an answer. This somewhat disheartening situation proved misleading. Tears were quickly followed by an apparent appreciation of what was happening, and the children gave surprisingly accurate accounts of the conversation to their parents.

Thoughtlessness on the part of the nurses sometimes led to increased anxiety. An 8 year old boy was moved to a more isolated part of the ward because he had been vomiting; he was given no reason for this and was intensely miserable. He said he had been "punished" for being naughty and for being a coward during the operation. This feeling of failure in relation to the other children was common. Children were intensely aware of their relationships with each other, and compared themselves in terms of bravery. Other children were often regarded as being punished when they were suddenly taken away for operation or investigations, the red blanket being cited as additional evidence for this. Sick children, particularly the burned children, were also a common focus for anxious fantasy.

35 of the 40 parents visited their children. The 5 who never visited (2 in group A and 3 in group B) happened to live near the hospital. They said to come would upset themselves too much.

Some of the mildly disturbed children in the ward became severely disturbed on returning home. They were either aggressive to their parents, particularly the mother and siblings, or over-dependent, following the mother about the house, and asking to be fed, bathed or dressed. Some of the most disturbed children in the ward were least so at home.

Six months after discharge, 14 children were still disturbed (11 in group A, and 3 in group B). 3 of these had not been disturbed at the one-week interview. They had been well behaved, quiet, and noticeably obedient for the first three weeks at home, and had then become restless and aggressive. These children may have waited until they felt secure at home before expressing their anxiety. As I have already mentioned, this situation is comparable to the over-compliant good behaviour shown by insecure children in the ward. Bedwetting and tics did not arise as complications.

Discussion

This investigation has two main interests: first, the extent to which these children were frightened and confused on admission; second, the lower incidence of disturbance after leaving the ward in the children who were specially prepared, coupled with the manifest relief and pleasure most of the children showed when they met a friendly adult who was not either doing something to them or asking questions.

An eye operation was chosen for this study because all the children would have the same hospital experience, and since the eye is a highly valued part of the body, it was thought that it would be a particularly disturbing operation. It might be argued that the results should not be applied to children admitted for other reasons; but this is not so, for the methods of thought which such a preparation aims to assist are common to all children of similar age and emotional development, whatever their physical illness.

Many of the children were told nothing, or very little by their parents when they were going into hospital, and some were even told direct lies; others formed alarming ideas based on what they had seen or heard, and here the "unpleasant" truth seemed less disturbing than their fantasy. They were helped considerably by the simple discussion and explanation.

The demonstration and talk, to be effective, must follow an extremely simple course, at the same time allowing the child adequate opportunity to express his feelings. There is a tendency to think of children, and to speak to them, as though they are either miniature adults at one extreme or uncomprehending animals at the other. But in fact a child of 4 years is quite different from a child of 6 years, and both are different in the range of their concepts and the form of their thought and emotion from an adult. They require accurate explanations—i.e., accurate in that they fit their own concepts—if they are to feel reassured.

These children clearly appreciated the contact made with them, and I think the main requirement of this preparatory interview was that the child should be left with a feeling that any fears were understood, and would be looked after, without his necessarily having had to express them in words

Unfamiliar and frightening surroundings and sights, and unsympathetic or thoughtless staff, increase the stress for the child, and it was interesting that in spite of having an experienced and understanding staff, much needless anxiety was caused by sudden changes in the ward routine, unexpected investigations, and a general failure to tell the children what was happening There was a tendency to treat children with little regard for their personal privacy, and to forget that they may be aware of what is going on around them and wish to understand it

Jessner and Kaplan (1948) have suggested that disturbed ward behaviour may be beneficial, as the child has been able to express his anxiety Certainly ward disturbance was common in the children who afterwards made a good recovery

The younger the child, the more dependent he is on his parents, and the more important is separation from the mother (Bowlby 1951), moreover, the less his skill in methods of dispelling fear, the more likely it is that these will fail him and that he will become emotionally disturbed It is a disquieting observation here that all the children under 4 years were still disturbed six months after discharge from the ward

One final comment I am not suggesting that every child should be interviewed by a psychiatrist before operation My clinical experience undoubtedly helped me in talking with these children, who were facing a critical time—left by their parents, in strange surroundings, and among strangers But this type of interview could be carried out by any person prepared to give the necessary time, to talk to the child in terms he can understand, and to allow him adequate opportunity to express his feelings Ideally, this person should almost certainly be one of the parents, and it seems advisable that they should be given some help in this task—if only by leaflet, letter, or a little briefing

Summary

40 children were admitted to hospital for an eye operation and followed up for six months Most of them were confused and frightened on admission Many had been told nothing, very little, or even direct lies, by their parents, and had formed alarming ideas about what was to happen

In a special interview on admission, the children were given a simple verbal explanation and reassurance A significant number of children aged $4^1/_2$ years and over benefited from this type of preparation

Many schemes of preparation have been recommended in recent years, some of them complicated This study suggests that the older child can obtain considerable benefit from a simple and systematic explanation opportunity to express his feelings, and the realisation that he will be understood and looked after while he is in hospital

I am indebted to the endowments committee of Guy's Hospital, who provided a grant which allowed the work to be carried out, Mr Frank Law and Mr O G Morgan, who kindly allowed me to see their patients, Miss S Cox, who undertook the psychological testing of the children, and the members of the staff of the department of child health for their kind coöperation

GLOSSITIS AND THE PRE-ANÆMIC STAGE OF PERNICIOUS ANÆMIA

DIAGNOSIS BY SIMPLE METHODS

J F Adams
M B, F R F P S, M R C P E, D Obst
REGISTRAR IN MEDICINE, THE WESTERN INFIRMARY, GLASGOW

ADDISONIAN pernicious anæmia is now regarded as a manifestation of vitamin-B_{12} deficiency, the development of anæmia being preceded by months or years of depletion of vitamin B_{12} in tissues and serum During this pre anæmic stage, the patient may complain of vague general ill health, and of symptoms, such as glossitis or neuropathy, suggesting vitamin B_{12} deficiency

It is the purpose of this paper to show that simple methods—gastric aspiration, bone marrow biopsy, and response to treatment with vitamin B_{12}—may establish the diagnosis of pernicious anæmia in the pre anæmic stage, once suspicion has been aroused by the presence of glossitis In the cases described the diagnosis was also confirmed by microbiological assay before treatment

Case-reports

Case 1 —A woman, aged 40, complained of soreness of the tongue of 8 months' duration The objective changes were gross, the tongue resembling raw beef Physical examination showed no abnormality, apart from the glossitis The peripheral blood was within normal limits hæmoglobin (Hb) 82% (=12 1 g per 100 ml), erythrocytes 4 31 × 10^6 per c mm packed cell volume (P C V) 39% Gastric aspiration revealed histamine fast achlorhydria, and the sternal marrow showed hyperplastic early megaloblastic erythropoiesis The diagnosis of vitamin B_{12} deficiency was confirmed by microbiological assay, the serum vitamin B_{12} being 40 µµg per ml (normal 100–900 µµg , mean 360 µµg) Parenteral administration of vitamin B_{12} caused complete subjective and objective improvement in the glossitis, but did not alter the blood levels

Case 2 —A woman, aged 76, complained of soreness of the tongue of a year's duration The tongue was smooth and, at the tip, red Physical examination was otherwise unrevealing The peripheral blood was normal (Hb 99%, P C V 42 5%) Histamine fast achlorhydria was found, and sternal marrow biopsy disclosed hyperplastic early megaloblastic erythropoiesis The serum vitamin B_{12} was 45 µµg per ml Parenteral vitamin B_{12} abolished the glossitis

Case 3 —A woman, aged 66, complained of glossitis for 5 years and dyspepsia for 2 Her tongue was smooth but not red There were no abnormal physical findings, and the peripheral blood was normal (Hb 104%, P C V 45%) Histamine fast achlorhydria was noted and the sternal marrow showed hyperplastic early megaloblastic erythropoiesis Barium meal examination and follow through were normal The serum vitamin-B_{12} was 120 µµg per ml Parenteral vitamin B_{12} relieved the glossitis but did not affect the dyspepsia

Discussion

Vitamin-B_{12} deficiency should be suspected in every case of glossitis where no other obvious cause is found It is still a common misconception that normal peripheral blood excludes such a diagnosis and renders further investigations unnecessary, though Ungley (1952) has reported a case of glossitis without anæmia but with a low serum-vitamin-B_{12}, and Mollin and Ross (1954) have shown that vitamin B_{12} deficiency can be demonstrated by microbiological assay in non anæmic patients

How commonly glossitis in non anæmic patients is due to vitamin-B_{12} deficiency is not known, for only one other comparable case has been reported (Ungley 1952), but the syndrome may not be rare, for the three cases reported here are half the cases of glossitis without anæmia seen in a year in a general medical unit These demonstrate clearly that the diagnosis can be established in the pre-anæmic stage In view of recent reports (Bastrup Madsen 1956a, Victor and Lear 1956) that the neurological lesions due to vitamin-B_{12} deficiency may progress even when the blood is normal, it is obviously desirable in such cases to begin treatment as soon as possible

In our patients the bone-marrow erythropoiesis was hyperplastic and undoubtedly megaloblastic, but the abnormality was not frank, and the abnormal cells were those described by Dacie and White (1949) as intermediate megaloblasts Mollin and Ross (1953) have shown that erythropoiesis becomes megaloblastic when the serum-vitamin B_{12} falls to about 80–120 µµg per ml At this borderline level the epithelial manifestations of vitamin-B_{12} deficiency, such as glossitis and cheilosis may precede the transition from normoblastic to megaloblastic erythropoiesis, in such cases there may be an abnormality in the maturation of the white-cell precursors (Bastrup-Madsen 1954, 1956b) but, unless erythropoiesis is megaloblastic, the more elaborate techniques of serum-vitamin-B_{12} estimation by microbiological assay or absorption studies with radioactive vitamin B_{12} are necessary to confirm or refute the diagnosis

The treatment of such patients does not differ from the treatment of those with established pernicious anæmia Glossitis has been observed in cases of pernicious anæmia in therapeutic remission maintained on 100 µg of vitamin B_{12} intramuscularly each month, and larger doses, as recommended by Davis (1957), should be given Failure to respond to treatment renders a diagnosis of vitamin-B_{12} deficiency untenable

Summary

Three cases of glossitis in non-anæmic patients are reported The diagnosis of vitamin-B_{12} deficiency was suspected from the demonstration of achlorhydria and of early megaloblastic change in the bone marrow It was confirmed by microbiological assay and by the response to treatment with vitamin B_{12} The value of gastric aspiration and bone-marrow biopsy in the detection of vitamin-B_{12} deficiency in non-anæmic patients is emphasised

I am grateful to Dr J A W McCluskie for his advice and criticism It is a pleasure to thank Dr D L Mollin, of the Postgraduate Medical School of London, for his most generous help and for the serum vitamin-B_{12} estimations

ATHEROSCLEROSIS IN A HÆMOPHILIAC

J W Stewart
M B Lond.
PATHOLOGIST

E D Acheson
M A, B.M Oxfd, M R C P
MEDICAL REGISTRAR

MIDDLESEX HOSPITAL, LONDON

The narrowing of the coronary arteries which may occur in atheroma is attributed by Duguid (1946, 1954) to the deposition of fibrin on the endothelial surface of the vessel wall In his view the other appearances which characterise the atheromatous plaque, such as fibrous thickening of the intima, and fatty infiltration, follow this primary event Thus Duguid writes "The only process likely to reduce its [i e, the artery's] lumen is one arising in the lumen itself, such as thrombosis or embolism, and we may therefore take it that, where a coronary artery is narrowed by a fibrous thickening of the intima, thrombosis is the most likely factor" (Duguid 1954) He admits that there may be a second type of lesion not preceded by intimal thrombosis As he says, "there are in fact, two forms of atherosclerosis—one in which there is narrowing, and which is consequently a highly dangerous condition, and another in which the tendency is rather in the opposite direction" He believes that the latter has little importance in the pathogenesis of ischæmic heart-disease In Duguid's view the fatal factor may be "some thrombogenic influence, more powerful and generalised than mere local damage to the vessel walls" (Duguid 1954)

We report here a case in which extensive atheroma of the coronary arteries and aorta has developed in spite of lifelong hæmophilia

Case-report

Retired storekeeper, aged 73 [hospital no A 34249] When a child he noticed that he bled excessively after cutting his finger When 25 years old he bled for a week after a tooth had been extracted Shortly afterwards he gave up cricket because of hæmorrhage into his knee joints From that time he remained well, except for a tendency to bruise easily, until 1928, when he passed blood in his urine for a week Ten years later, at the age of 54, he again had hæmaturia In view of a prolonged clotting-time ($11^{1}/_{2}$ minutes) and a normal bleeding-time hæmophilia was diagnosed Between January, 1945, and his death in March, 1957, he was admitted to hospital nine times with hæmorrhage from the alimentary tract and had to have blood transfusions on four occasions

Between these episodes of hæmorrhage his health was good until 1954, when he began to have retrosternal pain on climbing stairs, it was relieved by rest and with nitroglycerin. In 1955 the frequency of the attacks on exertion increased

There is no history of consanguinity The patient's maternal grandfather "bled to death" at the age of 67, and also two first cousins 24 and 28 The two sons of the patient's married daughter bleed easily and one is a proved hæmophiliac

Clinical and Laboratory Findings

On admission on Jan 6, 1957, he weighed 183 lb No clinical evidence of anæmia, petechiæ, or ecchymoses The tissues around both knee joints were hypertrophied, and crepitus was palpable on moving these joints Cardiovascular system sinus rhythm, blood-pressure 150/80 mm Hg, apex-beat impalpable, first and second heart sounds audible, no systolic or diastolic murmur Respiratory, alimentary, and central nervous systems normal While dressing and undressing the patient had two typical attacks of angina pectoris

Examination of the blood showed Hb 103% (14 9 g per 100 ml), white cells 11,200 per c mm, platelets 210,000 per c mm, coagulation-time $15^{1}/_{2}$ minutes (Lee and White), clot retraction nil, prothrombin time 12 seconds, prothrombin consumption 100%, Wassermann reaction negative The total blood cholesterol was 240 mg per 100 ml The α lipoproteins were 32 mg per 100 ml (13%), and β lipoproteins 243 mg per 100 ml (87%) by the Cohn microfractionation method no 10 A thromboplastin generation test gave the following results

	Patient (sec)	*Patient + normal serum (sec)*	*Patient + 50% normal $Al(OH)_2$ plasma (sec)*	*Patient + 50% hæmophiliac aluminised plasma (sec)*
2 min	60	100	43	160
3 min.	37	70	22	90
4 min	30	36	18	
5 min	26	33	14 5	39

On X ray screening of the chest, the left ventricle was seen to be prominent and the aorta unfolded No calcification was visible in the coronary arteries or in the aortic valves Parallel linear calcification was clearly visible in the abdominal aorta, and there was a trace of calcification in the aortic arch

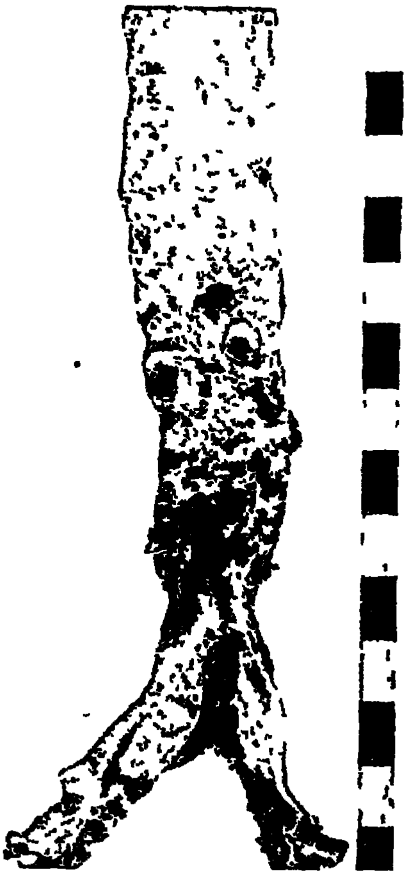
Electrocardiography on April 10, 1955 had shown sinus rhythm, P–R and QRS intervals normal, QRS complex normal, and horizontal RS–T depression of 1 5 mm in V4 and V5, and of 1 0 mm in I II, and V6 These changes are highly suggestive of myocardial ischæmia

Post mortem Findings

After another admission to hospital for melæna on March 10 the patient died on March 13 in spite of blood transfusion We are indebted to Dr P S Andrews, of the Bland Sutton Institute, for his report on the necropsy

The body was obese (weight 170 lb) and the skin pale The heart was enlarged from left ventricular hypertrophy and weighed 500 g the muscle showed ischæmic fibrosis of the septum and the lateral wall of the left ventricle The coronary arteries were atheromatous and calcified, the lumen being narrowed and tortuous but no recent occlusion was present The aorta showed early atheromatous yellow streaks in the thoracic part and calcified ulcerated atheroma in the abdomen (see figure). The major branches as well as the cerebral arteries were also atheromatous.

An apoplectic cyst was present in the left putamen. The kidneys showed nephrosclerosis. The immediate cause of death was hæmorrhage into the lower ileum, for which no local cause was found.



Aorta with atheromatous lesions (inch scale)

Discussion

Our patient had two attacks of hæmaturia and at least nine of melæna, and no adequate local cause for these was found. He also had hæmarthrosis and excessive hæmorrhage from minor trauma, as well as a lifelong tendency to bruise easily. Clinically he appeared to have moderately severe hæmophilia.

The results of the hæmatological investigations confirm a disorder of coagulation. The thromboplastin-generation test indicates conclusively that there was a deficiency of antihæmophilic globulin, and therefore that the patient was a hæmophiliac. His past and family history is typical of hæmophilia.

To have reached the age of 73 is remarkable for a hæmophiliac, but it is fair to say that but for blood-transfusion he would probably have died earlier. His history suggests that his tendency to bleed may have become more pronounced in the past ten years.

In the ordinary course of events this patient would not have been thought liable to thrombosis. Indeed both clinical and hæmatological evidence suggest that he could not form a firm thrombus in bleeding vessels. It is therefore difficult to believe that "some thrombogenic influence" (as postulated by Duguid) was an important factor in narrowing his coronary arteries in later life, unless the deposition of fibrin, which Duguid believes to be important, takes place independently of the ordinary coagulation processes.

Summary

The case is reported of a hæmophiliac, aged 73, who had angina pectoris.

His myocardial ischæmia was due to atheroma of the coronary arteries. Extensive aortic atheroma was also found.

This case is discussed in relation to Duguid's theory of the causation of atheroma by intimal thrombosis.

We wish to thank Dr H. L. Marriott for permission to publish, and Dr J. N. Pattinson for the radiographic examination. The cholesterol and lipoprotein estimations were performed by Dr G. L. Mills in the Courtauld Institute of Biochemistry, Middlesex Hospital.

CLICKING PNEUMOTHORAX SIMULATING MYOCARDIAL INFARCTION

Geoffrey Bourne
M.D. Lond., F.R.C.P.
PHYSICIAN IN CHARGE OF THE CARDIOLOGICAL DEPARTMENT, ST. BARTHOLOMEW'S HOSPITAL, LONDON

The diagnostic problem raised in this case was due to the association of very severe chest pain with an audible systolic click and electrocardiographic changes. Suspicion was at first aroused by the severity of the pain, which suggested myocardial infarction at an unusually early age.

Case-report

A man, aged 22, had had no illnesses except severe whooping cough at the age of 5, when he had bronchopneumonia and was ill for six weeks. He was very well throughout his military service and was playing tough rugby football four days before his pain began.

The pain started in the back of the left shoulder, and radiated to the left side and to the front of the chest. For ten minutes he did not pay much attention to it, but it soon became so acute that he took a taxi on his way home. It remained severe for only about half an hour. That evening Dr A. R. Kelsall noticed a loud click in the chest which was audible by the unaided ear. This synchronised with the heart beat and was best heard, by stethoscope, near the left sternal border. The click was particularly obvious when he was lying flat or reclining, but went when he stood up. When I saw him next day he had had no further acute pain, but only momentary twinges, particularly on taking a deep breath, or on sitting up after being flat, especially if he did not use his arms. He had had no hiccup, no dysphagia, and in fact no other symptoms of any sort. Dr Kelsall had taken an electrocardiogram which showed inversion of the T wave in leads 2, 3, and VF.

Examination

He looked well but a little pale. The heart rate was 68, the rhythm regular except for a very occasional premature beat, and the blood pressure 130/70 mm. Hg. The pulmonary second sound was accentuated and sometimes reduplicated. The exocardial click was harsh and loud, particularly halfway through inspiration. It was at its maximum just before the second sound, and hints of it were present during diastole. I could detect no clinical abnormality of the lungs or abdominal organs. The erythrocyte sedimentation rate and white cell count were normal. In the electrocardiogram which I took the T wave in lead 2 was flat, and so were the P waves; this was associated with considerable bradycardia, which I took to be nodal. The T wave was inverted in leads 3 and aVF, but no Q waves were present in either lead. The T waves were also rather lower than normal in leads V6 and V7. I was not quite happy about the left lung in the anteroposterior radiograph. The markings suggested to me the possibility of slight cystic or emphysematous change.

Diagnosis

I decided first of all that he had not had a myocardial infarction, and secondly that the sound was exocardial and not pericardial. The most probable explanation was that some adhesions had formed around his lung at the time of his whooping cough bronchopneumonia, and that the strenuous game of football had begun a tear at this point which caused an encysted localised pneumothorax. A pneumothorax can produce electrocardiographic abnormalities, and I thought that the changes in his electrocardiograms could be ascribed to this cause. I advised that he should stop at home for two weeks, being up and about, and that he should then have a further week of greater activity.

Five Weeks Later

He remained symptom free and in a state of increasing eagerness to resume his club football. At my re-examination five weeks after the first, he said that he felt perfectly fit. He was free from aches or pains and had not been short of breath. He had not noticed any more of the audible clicking from his heart area.

I could find no clinical abnormality. The electrocardiogram had improved. The inversion of the T wave in lead aVF had disappeared. The T wave now was still inverted in lead 3 and flat in aVF; in both, it remained so on full inspiration.

He had also a wandering pacemaker (the P–R interval shortened to 0 05 sec but on full inspiration lengthened immediately to 0 12 sec, and in other parts of the tracing it was normal at 0 18 sec) Radiologically the heart was normal in size and shape The transverse diameter of the heart by orthodiagraph was 13 5 cm and that of the chest 30 0 cm

Thus his heart was normal The T-wave inversion was regarded as postural, particularly as no Q waves were visible in leads 3, aVF, or V7 His pneumothorax had healed

Dr Clifford Hoyle said that the chances of recurrence were in the neighbourhood of 10 to 1 against, and thought that from the pulmonary point of view he might resume his football I felt that this course would be safe from the cardiological aspect Should there be a recurrence, no permanent damage would be done

Additional Radiological Information

Dr Horace Post reported on the X-ray films taken within twenty-four hours of the onset of symptoms He could see no cystic or emphysematous lesion, no air in the mediastinum, nor any minor pneumothorax (though the postero anterior view did not cover the periphery of the left base) There were some old right basal pleural adhesions and old, very minor, peribronchial thickening in the right lower lobe, but no evidence of any tuberculous infiltration The heart and aorta were normal

Discussion

There are two points of diagnostic interest The first was the very loud systolic click, and the second the changes in the T wave in leads 2, 3, and VF in the electrocardiogram The more important of these, and the one giving the most definite lead, was the loud audible systolic click There is no other intrathoracic condition which can give rise to such a loud noise, and the diagnosis of small local encysted pneumothorax near the heart seemed to be inevitably correct, even though the films failed to reveal it No myocardial infarction could possibly give rise to this clinical picture On the other hand the T-wave changes, particularly those in lead 2, in association with very severe chest pain, provided graphic and visible evidence pointing in a somewhat sinister fashion to a possible posterior myocardial infarct in a young man

The clinical picture of clicking pneumothorax has been well painted by Scadding and Wood (1939), who append a considerable bibliography

They quote 4 cases of spontaneous pneumothorax and 2 of artificial pneumothorax with loud clicking sounds coming from the left chest In 2 of their 4 spontaneous cases the click was easily audible by the unaided ear In all cases either the sound or the pain or both were influenced by posture All their 4 cases were in males between the ages of 16 and 26 In only 1 is there record of an electrocardiogram, and in that case the changes were those of the Wolff-Parkinson White syndrome

Electrocardiographic changes can be produced by pneumothorax, usually, it must be admitted, as a result of changes in the axis or in the degree of rotation of the heart secondary to the presence of air in the pleural cavity Spontaneous mediastinal emphysema is another condition in which chest pain, exocardial sounds, and electrocardiographic changes have been recorded In more than one such case the suspicion of myocardial infarction has been raised

Pain was present in 6 out of 9 such patients in the series of Aisner and Franco (1949), it can be very severe It is usually to one side or other of the midline but may be central It does not last more than a few days The systolic click in Aisner and Franco's series was audible or felt as a creak by the patient in 4 of the 9 cases It does not appear to have been as loud as the clicking sound mentioned by Scadding and Wood or noticed in the present case In several of the recorded cases this click has been noticed, both by the patients and by the physicians, to vary considerably with posture Electrocardiographic changes were mentioned by Aisner and Franco, who referred to changes in the T waves and S–T segments Holoubek's (1953) patient suffered a sudden collapse with the development of auricular fibrillation and shock The S–T segment was elevated in lead 1 and depressed in leads 2, 3, and 4R These abnormalities were no longer present next day Miller (1945) reports a case in which pain, shortness of breath, and electrocardiographic changes raised the suspicion of an organic cardiac cause Here there was pain, shortness of breath, loud exocardial sounds varying with posture, and flattening of the T waves in lead 1 with S–T elevation in leads 2 and 3 These changes subsided after twelve days

Spontaneous pneumothorax and spontaneous mediastinal emphysema can clearly have a common origin—indeed they often coexist Of 39 cases of spontaneous mediastinal emphysema recorded by Fagin and Schwab (1946), 21 had definite evidence of spontaneous pneumothorax also In the present case the symptoms and signs thus seem to be due to a combination of these two lesions, the pneumothorax being so small that it was not detected by skilled radiologists, and the spontaneous mediastinal emphysema localised in such a way as to have given rise to electrocardiographic changes

Preliminary Communication

AUTO-ANTIBODIES IN ADDISON'S DISEASE

THE recent work of Witebsky and his colleagues [1] [2] has shown that immunisation of rabbits by rabbit thyroid tissue results in the development of organ specific antibody, accompanied by pathological changes in the animal's own thyroid gland Roitt et al [3] have demonstrated, by the precipitin test, anti-thyroid antibody in the serum of cases of Hashimoto's disease We present evidence here that the association of auto-antibody with thyroid disease may be an illustration of a wider phenomenon, insofar as the same principle may apply to adreno cortical atrophy in some cases of Addison's disease

MATERIALS AND METHODS

Extracts of human organs (liver, kidney, brain, thyroid, and adrenal) were prepared from post mortem material obtained within three hours of death and also from thyroid and adrenal tissue excised surgically Suitably sized pieces of the various organs were frozen, finely sliced, and extracted with saline solution in a mechanical shaker The extracts, freed of most of the suspended tissue fragments and lipoid by centrifugalisation, and diluted when necessary to reduce anticomplementary activity, were used as antigens Tests for antibodies were performed by the complement fixation reaction as follows

0 1 ml of the patient's inactivated serum was incubated at 37°C for 1 hour with 0 1 ml of antigen and 3 hæmolytic doses of guineapig complement 0 5 ml of 3% suspension of sheep cells sensitised with immune horse serum, was added, and examined for lysis after a further period at 37°C Sera showing anticomplementary activity were discarded

Sera were examined from patients with Addison's disease (10 cases), Hashimoto's disease (18), thyrotoxicosis (13), and Simmonds's disease (2), and from 55 patients in general medical and surgical wards who were not regarded as having any specific endocrine disturbance In 2 of the cases of Addison's disease there was evidence of tuberculosis The results are summarised in the accompanying table

Fixation of complement observed in these tests cannot be attributed to ABO blood group incompatibility of serum and tissue extract Tests were performed with several specimens of each tissue extract, and it was found

26–43	Hashimoto's disease	+ or ++	–	–
44–98	Various other diseases	3 + or ++, 52 –	–	–

– = Complete lysis + = Partial lysis ++ = No lysis
* Selected cases (vide infra)

that the degree of complement fixation varied with different thyroid and adrenal extracts In cases 1 and 2 the titres of the sera for complete inhibition of lysis varied between 0 and 16 with different adrenal extracts even with the weakest reacting extracts, however, partial inhibition of lysis was observed, whereas all the other sera were completely negative with all the adrenal extracts

DISCUSSION

In an investigation still in progress we have found that the serum of almost all cases of Hashimoto's disease and of approximately 50% of cases of thyrotoxicosis contain complement fixing antibodies reacting with thyroid extract In the present investigation, sera chosen for this property (cases 13–43) did not react with adrenal extracts We therefore conclude that cases 1 and 2 possess, in addition to thyroid antibody, an antibody to adrenal tissue It is uncertain whether this latter antibody plays an important part in the destruction of the adrenal cortex in idiopathic Addison's disease, but we present below evidence which inclines us to this view

Wells[4] drew attention to pathological changes in the thyroid gland in cases of idiopathic Addison's disease—namely, diffuse lymphocytic infiltration, formation of lymphoid follicles, loss of many of the thyroid acini, and eosinophilia of the epithelium of the surviving acini These changes, which appear similar to, but less pronounced than, those of Hashimoto's disease, were infrequent and slight in tuberculous Addison's disease Similar findings are reported by Sloper[5] Wells noted that the adrenal cortical atrophy in his idiopathic cases was accompanied by lymphocytic infiltration and regenerative foci of enlarged eosinophilic cortical cells He concluded that the changes in the thyroid and adrenal cortex were of the same nature, and attributed them to the long-continued action of a toxic agent The demonstration of both adrenal and thyroid antibodies in cases 1 and 2 supplies a possible explanation for Wells's observations As illustrated by cases 44–98, complement fixing antibody to thyroid extract is sometimes present in patients without overt thyroid disease when opportunity has presented, we have carried out subsequent post mortem examination of such unexplained positive cases, and have observed in the thyroid gland changes similar to those observed by Wells in idiopathic Addison's disease There is therefore some evidence that the presence of complement fixing antibody to thyroid extract is not unaccompanied by pathological changes in the thyroid

The work of Witebsky and of Roitt provides evidence that antibody to thyroid tissue is responsible for the changes of Hashimoto's disease By analogy, we infer that the antiadrenal antibody may be responsible for progressive destruction of the adrenal cortex in idiopathic Addison's disease We suggest that some cases of Addison's disease are prone to form both adrenal and thyroid auto antibodies, the latter antibody accounts for the histological changes usually present in the thyroid gland, and when particularly strong is detectable by the precipitin test and explains the coexistence of Hashimoto's disease and Addison's disease as in our case 2 The negative results of complement-fixation tests in cases 3–8 do not rule out these conclusions, for it may well be that cessation of adrenocortical destruction is accompanied by disappearance of the anti adrenal antibody, just as precipitating anti-thyroid antibody is frequently not detectable in the serum of cases of Hashimoto's disease after surgical removal of the major part of the thyroid gland Alternatively, some or all of our cases 3–8 may have tuberculosis of the adrenal glands, or it may be that auto antibody is only one of a number of agents which may affect adrenocortical destruction, and operates in only a proportion of cases of idiopathic Addison's disease

We acknowledge with pleasure our indebtedness to the physicians and surgeons who have willingly coöperated in providing us with specimens of blood, surgical material, and access to their case records, and to Prof D F Cappell for advice and criticism This investigation was assisted by a financial grant to one of us (J R A) by the Department of Health for Scotland

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE

Laboratory Aspects of Amœbiasis

A MEETING of the society on May 16, with the president, Prof R M GORDON, in the chair, discussed the laboratory aspects of amœbiasis

Dr C A HOARE remarked that the ætiology of amœbiasis still needed elucidation, and that account must be taken of the fact that two races of *Entamœba histolytica* existed—the large race which was pathogenic, and the small race which was not pathogenic, was found only in the lumen of the bowel, and did not invade the tissues Parts of the life cycle of the small race were not yet known

Group Captain W P STAMM reviewed the methods of diagnosis currently used He agreed that the small race was non-pathogenic He had nothing good to say about the complement-fixation test, conscientious direct examination of specimens was as good as anything The view that any abdominal complaints associated with the presence of *E histolytica* in the fæces were invariably due to amœbiasis was to be deplored A series of 181 Pakistani aircraft apprentices had each had 3 consecutive stools examined every year for three years, 101 apprentices were found to be positive at least once, yet only 1 had symptoms severe enough to bring him to hospital for treatment of amœbiasis Moreover, a carrier rate of 6% was found in 724 symptomless ex overseas patients About 50% of Europeans with amœbic hepatitis or liver abscess had no demonstrable *E histolytica* in their stools

Dr R A NEAL discussed virulence, making the point that the kitten, commonly used in experiments, was so susceptible that the results might give an exaggerated impression of virulence Young rats were better, and a method of scoring on the basis of ulceration of the cæcum of infected rats had been used In this way, strains from acute cases were found to be virulent, and strains from carriers were non-virulent Virulent strains maintained in culture lost much of their virulence, but this could be restored by liver passage Investigation of various strains, in association with bacteria of different origins and species, had indicated that, though the presence of bacteria was essential for the amœbæ, it was the amœbæ themselves that were invasive and responsible for the lesions But the difference in virulence between strains of the large race from acute cases and carriers suggested that the large race itself was represented by two types Infection of man with the virulent type must pass through a quiescent phase when the disease did not arise, to ensure survival by the production of cysts

---

[4] Wells H G *Arch Path* 1930 10 499
[5] Sloper, J C *J Path Bact* 1953 66 53

Dr G **Woolfe** described the process of screening large numbers of compounds in the search for new amœbicidal drugs In vitro tests in capillary tubes containing the amœbæ in culture medium with dilutions of the drug determined those which were amœbicidal in high dilution, and these were chosen for in-vivo/in-vitro tests, in which the drug was given by stomach-tube to young uninfected rats These were killed five hours later, and the cæcal contents tested for amœbicidal capacity by the in-vitro method In-vivo tests were then carried out in weanling rats

In the discussion Dr J D **Fulton** suggested that culture was perhaps more useful in diagnosis than was sometimes thought, and that the complement-fixation test was helpful in extra intestinal amœbiasis

Prof A W **Woodruff** said that, in amœbiasis, the clinician relied heavily on laboratory diagnosis, and he referred to the many occasions on which courses of anti-amœbic treatment were given without secure diagnosis, with resulting neurosis

Dr H C **Trowell** commented on the difficulty of diagnosis even if the laboratory report was positive The presence of the amœbæ was not enough—there must be clinical evidence of illness which could be attributed to that infection Almost every African in Uganda was a carrier Neurosis was much commoner than true amœbiasis

Lieutenant Colonel J H **Walters** raised the question whether persons passing cysts but having no bowel trouble should be given anti-amœbic treatment There was danger, he thought, in leaving them untreated, since liver abscess often developed in patients with no history of former attacks He therefore thought it unwise not to treat carriers of cysts—which might be virulent

Brigadier J S K **Boyd** recalled the old rule that, if amœbæ were found which were actively motile and contained red cells, the diagnosis of acute dysentery could be made, and in that condition they would be found if looked for carefully

Sir **George McRobert** emphasised that the patient should not have had anti amœbic treatment before the laboratory examination, since it would eliminate cysts Clinicians accepted emetine bismuth iodide as the best drug now available, but they were not satisfied with it

New Inventions

A METHOD OF DETERMINING THE pH OF THE BLOOD AT THE BEDSIDE

Until recently the determination of the pH of the blood has been a laboratory procedure A sample is withdrawn and removed to the laboratory, where it is transferred into the glass electrode system which is kept at room-temperature After determination of the pH at room-temperature, correction is made to body-temperature with the aid of tables [1]

By means of the system described below, in which a pH electrode is contained in the plunger of a syringe, it is now possible to measure blood pH at 37 5°C at the bedside The apparatus has been constructed in such a way that it is suitable for use in the wards, and readings of the pH of the blood can be made at the bedside at five-minute intervals

A sample is taken directly into the syringe electrode, and this is connected to the rest of the electrode system, all of which is kept in a water-bath at body-temperature In this way one can follow the changes in the pH of the blood in metabolic disorders, in respiratory or renal failure, under changing experimental conditions, and during anæsthesia The advantage of measuring the pH at body-temperature is evident

THE APPARATUS

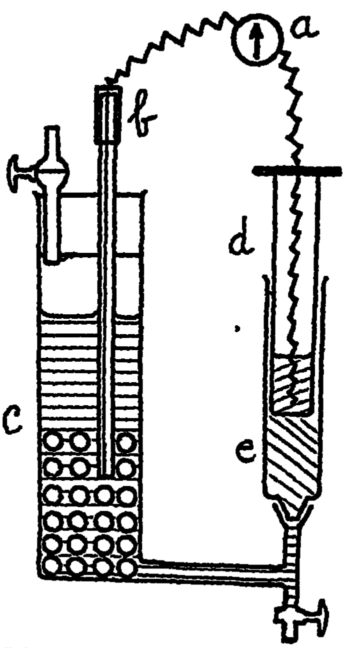
The electrode system consists of a glass U tube with unequal limbs, of which one is 10 0 cm long and 1 5 cm in internal diameter, and the other limb is 1 cm long and has the internal dimensions of a female Luer joint At the lowest point of the U-tube is a drainage tube 1 cm long bearing a glass stopcock The long limb of the U tube is filled with a supersaturated solution of potassium chloride, into which dips the calomel reference electrode supported in position by a rubber bung which fits into the top of the long limb The rubber bung also supports a small glass stopcock, which when opened to the atmosphere allows potassium chloride solution to flow from the long limb into the short limb If the stopcock is closed, the flow of potassium chloride ceases The syringe electrode which has a male Luer tip fits directly into the short limb of the U tube

The electrode system is held on a 'Perspex' support which can be raised or lowered into the water bath

The water bath is a perspex box measuring 20 × 20 × 15 cm It has a removable lid, and the electrode system can be lowered into the bath through a hole in the lid Other holes in the lid allow a thermometer, a thermostat, a 300 watt immersion heater, and a stirrer to dip into the water Further holes support test tubes which contain standard buffer solutions, potassium chloride, sterile heparin and saline solution, and sterile distilled water, which are kept at body temperature

TECHNIQUE OF MEASUREMENT

The water bath is kept permanently at 37 5°C The pH-meter, which is battery operated, must be switched on one hour before any measurements are made



Scheme of apparatus a, pH-meter, b, calomel electrode, c, supersaturated potassium-chloride solution d glass electrode, e barrel of syringe

The syringe electrode is washed out three times with buffer solution and then half filled with this solution The plunger is maintained in position by a small rubber band, which can be slipped along the plunger after all bubbles of air have been excluded The U-tube is raised from the water-bath, and the syringe electrode is fitted into the short limb before the electrode system is lowered into the water-bath It is allowed to remain there until the temperature of the buffer reaches 37 5°C, after which the meter is adjusted to this standard buffer solution

The electrode system is then raised, the syringe is disconnected, and the buffer solution is discarded A small glass stopper is fitted into the short limb of the U tube, which is then lowered into the water bath to keep it at the correct temperature until a sample of blood has been collected

---

[1] Rosenthal T B *J biol Chem* 1918 173, 25

The syringe electrode is flushed several times with the heparin saline solution, which has been kept immersed in the water bath, and the dead space of the syringe is filled with this solution to prevent clotting A sample of blood is then withdrawn through a Riley needle The U tube is raised from the bath, the sample is fitted into the short limb, and the electrode system lowered again into the water bath The whole manœuvre is carried out as quickly as possible, to minimise loss of heat

The pH falls as the blood warms up to 37 5°C over two or three minutes It then remains steady for some time before metabolic changes in the blood lower it Once equilibrium has been reached, the sample can be discarded, the syringe electrode washed out, and the short limb of the U-tube flushed with a little potassium chloride solution from the long limb The whole process, including standardisation if necessary, can be repeated on another sample

The pH of the blood can be measured to an accuracy of ±0 02 of a pH unit

PRECAUTIONS

The heparin saline solution should contain very dilute heparin because this substance has a considerable buffer capacity and, when used at full strength, lowers the pH of the blood A solution of 1 ml of heparin in 200 ml of physiological saline solution prevents clotting and does not affect the pH of the blood

To avoid contamination, the electrode system must be washed out with several flushings of each solution

With battery operated meters, the battery must be kept at full strength if the meter is to remain stable For this purpose a trickle charger is incorporated in the apparatus

The thermostat and heater may give rise to electrical interference, which may upset the pH meter All electrical components should be earthed, low voltage relays used, and a suitable condenser fitted to suppress the spark which flashes when the thermostat switches on and off

An induction motor should be used for the stirrer because brush motors set up electrical interference

This apparatus is obtainable from Electronic Instruments Ltd, Lower Mortlake Road, Richmond, Surrey

Reviews of Books

Pediatric Cardiology

ALEXANDER S NADAS, M D, F A A P, assistant clinical professor of pediatrics, Harvard Medical School, physician, Sharon Cardiovascular Unit, Children's Medical Center, Boston, Mass Philadelphia and London W B Saunders 1957 Pp 587 84*s*

THE appearance of the first complete textbook on heart-disease in children indicates the important place in medicine that this subject now holds

Most of the excellent works lately written on congenital heart-disease have looked from the viewpoint of the physician who normally deals with adults Dr Nadas, however, is a pediatrician as well as a cardiologist, and his book clearly reflects both these loyalties, which enhances its value as a practical treatise His observations are based solely on personal experience and not on information obtained by other people This approach has many advantages, but it does mean that some fields are not as widely covered as others, thus, more space might have been given to the surgery of certain conditions in infancy, in view of the high mortality of congenital heart-disease in the first year of life

In a preface Dr Nadas says he is writing for the pediatrician, the general physician, and the medical student There is much, however, which will interest the cardiologist, and the chapter on the electrocardiogram in childhood is of particular value Though the main emphasis is on congenital heart disease, the section on acquired disease is excellent, especially the chapter on rheumatic fever, which assesses very fairly the use of steroid therapy There is a well illustrated chapter on phonocardiography, but not everyone will agree with the interpretation of the nature of the first heart sound

In the accounts of congenital heart disease, clinical description is prominent and the essential hæmodynamic changes are shown in simple diagrams

A chapter on anæsthesia for children with heart disease will be a great help to those who must take decisions on this difficult question

Dr Nadas's father was a writer, which may be one reason why he has managed to make a book so full of facts both amusing and extremely readable

Treatment of Fractures

Vol II 5th ed Prof LORENZ BÖHLER M D director of the Accident Hospital and professor of accident surgery Vienna Translated from the 13th German edition New York and London Grune & Stratton 1957 Pp 1508 123s

VOL I of the new translation of the 13th German edition of this classic work appeared last year (see *Lancet*, 1956, ii, 1141) Vol II covers the injuries of the lower limb as far as the knee, and fascinating reading it makes It is in the femur especially that Böhler has had to modify his originally strong feelings against open fixation of fractures But metallic fixation is far from foolproof, and his accounts of the complications of maltreatment are as dramatic as ever This is an inspiring book, the illustrations are better than in the first volume, and in the text only the section on slipped upper femoral epiphysis is not fully satisfying

The Breasts and Breast Feeding

HAROLD WALLER, M B, F R C O G, formerly pædiatrician to the British Hospital for Mothers and Babies and the Poplar Hospital London Heinemann Medical Books 1957 Pp 56 7*s* 6*d*

IT is fortunate that Dr Waller, who had devoted much of his life to the study of human lactation, should have written down shortly before his death this brief but comprehensive account of his findings First published as a chapter in a textbook of obstetrics, Dr Waller's work now appears as a book He explains how failure of lactation is commonly caused by a period of over distension of the mammary gland and he goes on to describe the antenatal care and the management of the onset of lactation which have been evolved at the British Hospital for Mothers and Babies to avoid this hindrance The account is characteristic of Dr Waller, with its modest but fastidious use of language, its consistent logical teaching, and the impelling force of independent long, and patient clinical observation For these virtues it should remain a classic

Human Blood Coagulation and its Disorders (2nd ed Oxford Blackwell Scientific Publications 1957 Pp 476 42*s*)—Into the second edition of their book, Dr Rosemary Biggs and Dr R G Macfarlane have assimilated the discovery of the Christmas factor and other changes in knowledge about thromboplastin The general arrangement remains the same but the whole text has been revised in detail, at the small cost of 70 extra pages It is interesting to see that the theory of blood coagulation is now presented by a single diagram and apart from Christmas factor only "prothrombinase" is new A glossary of terms is a useful appendix The revision is so extensive that those who own the first edition will want to replace it by this excellent successor

Nursing and Diseases of Sick Children, for Nurses (6th ed London H K Lewis 1957 Pp 726 50s)—Edited by Prof Alan Moncrieff and Dr A P Norman, this textbook is written by many teachers at the Hospital for Sick Children, Great Ormond Street In tune with the modern emphasis on keeping children out of hospital the new edition contains more about the normal child, nursing at home and social and preventive medicine The comprehensive account of the medical and surgical treatment of children in hospital ranges from cupping and leeches to procainamide

THE LANCET

LONDON SATURDAY, JUNE 1, 1957

Consultant and Specialist

In the nine short years since the start of the National Health Service the work of hospitals has changed remarkably. Medical progress has led to contraction of some specialties, such as tuberculosis and hospital pædiatrics, and to expansion of others, such as cardiac surgery; but these changes, striking in themselves, have been overshadowed by the generally increased demand traceable to the disclosure, through the health service, of the population's full need for care.

In many hospitals the medical staffs do not suffice to meet the new demands. The teaching hospitals, in their privileged and largely protected position, are in no acute difficulty; but elsewhere the story is different. The public were quick to note the upgrading of peripheral hospitals and have responded by attending these instead of travelling, as once they would have done, to the teaching centre. In trying to fulfil their new responsibilities the peripheral hospitals are impeded by deficiencies not only in staffs but also in buildings and equipment. These deficiencies are related; for, as is seen from our survey on p. 1133, the appointment of much-needed surgeons, pathologists, or physicians may have to await the completion of new operating-theatres, laboratories, or wards. Nevertheless, it would be quite wrong to suppose that additions to clinical staff must all be deferred until new buildings have gone up. With ingenuity most busy outpatient departments could manage a few more sessions a week; and so could some operating-theatres. Nor is there any lack of suitable people for the work: in the main clinical subjects, and in some others, too many competent doctors are competing for what few consultant posts there are. The main difficulty lies elsewhere. Many clinical consultants find that their need for help does not extend over the whole range of their work: thus the physician might get along well if relieved of some of his outpatients, and the general surgeon if some of the operating were taken off his hands. A hospital authority, however, can hardly create a fresh consultant post for such restricted work; and, even if willing, it may be unable to do so because of lack of the beds and of the junior staff, including perhaps a registrar, needed to place a new consultant on a par with his colleagues. There is one way, and perhaps only one, in which such work can suitably be done without creating new units—namely, by the appointment of assistant physicians and assistant surgeons. The need for these is emphasised by the march of events in the many hospitals where it is proving impossible to find new senior registrars.

Noting that when it comes to applying for a consultant post, senior registrars in peripheral hospitals are at a disadvantage compared with their teaching-hospital contemporaries, registrars are shunning the non-teaching hospitals; and the consultants in these hospitals are having to undertake work that might be done by a junior colleague. Such a situation would be partly avoided if all senior registrars divided their time between teaching and non-teaching hospitals under a joint-appointments scheme. These schemes provide diversity of experience and ensure that no senior registrar who participates disqualifies himself for advancement simply by not working in a teaching hospital. But though in a few regions such a scheme is operating satisfactorily, in others, which seem to be more numerous, a scheme tentatively started has run into difficulties and has even had to be abandoned, because of incomplete understanding and possibly suspicion between the two hospital authorities or because of the reluctance of senior registrars appointed to the teaching hospital to move to the periphery. We believe that the country should be surveyed region by region to define the causes of success and failure, and to see whether in fact these schemes can possibly be extended; for in regions where there is no hope of their being operated successfully the appointment of senior registrars to peripheral hospitals should be discontinued, and the sooner this is done the better.

The new grade of assistant physician and surgeon might be expected to attract both senior registrars and S.H.M.O.s. For most it would be a step on the ladder to a consultant post (a step at a point where some senior registrars are at present being thrown off into mid-air), but others would be content to remain at this level. (One of the faults of the existing arrangement is that those who wish to make a career in one of the main clinical subjects, but may not even want to become consultants, are denied the opportunity.) The clinicians in this specialist grade would have a few beds; but they would be responsible to a consultant. Their remuneration should, we suggest, be spread over a wide scale, starting near the top of the present S.H.M.O. scale and stretching, with continuing service, well into the consultant's reaches.

To create a specialist grade of this kind would be to return to realities—to recognise the facts as they are today and as they were long before the National Health Service was thought of. The Spens Committee, so wise in many ways, ignored one big fact when it left no place in its scheme for the many doctors in our hospitals who are neither trainees nor consultants, but are certainly specialists; and, though the gap has been filled by calling them hospital medical officers, their morale has been damaged because even the most senior are paid less than a young consultant and because even the most junior feels himself out of the running for a consultant post. The Spens Committee was wrong, too, when it presumed that in an organised service the senior registrar would become a consultant about the age of 32, soon after finishing his formal training, or, if not, would (and should) find work elsewhere—in general practice or outside the N.H.S. Whereas in the old days the future consultant, in his 30s, often had to be content with small and miscellaneous appointments, through which, gaining experience, he worked his way up to major responsibilities, the Spens Committee prescribed an immediate long leap for everybody—with removal from the hospital service as penalty for anybody who could not jump the widening chasm. Because it has been so obvious that the hospitals need them, the majority have not in fact been asked to pay this penalty; but they have undergone, and are still undergoing, grave hardship; and because they are denied promotion the hospitals are often denied the full help they could give. Over six years ago we remarked[1] that senior registrars were doing advanced work satisfactorily, "and it seems a little odd to tell them that they must forthwith stop doing it because, now that their training is over, our principles forbid us to offer them anything less than the consultant posts they cannot get"

---

[1] *Lancet*, 1950, ii, 749.

Beneath the reluctance to face this situation has lain an undercurrent of fear that if a grade of specialists were created the Ministry of Health might ruthlessly swell its ranks with the aim of securing cut-price consultants Such a fear is surely baseless It would be for the profession to agree by negotiation on the ratio of specialists to consultants[2], and thereafter professional bodies would ensure that the agreement was observed The picture of a conscienceless group of Civil Servants riding roughshod over a supine medical mass is out of keeping with facts Our representatives have had no difficulty in securing the strict observance of the agreement for limitation of S H M O posts, and there is no reason why they should be less successful with those for specialists The proposal to introduce a specialist grade deserves fresh and unprejudiced attention

Antibiotics and Sore Throat

ANTIBIOTICS are expensive and not without risk Should they be used routinely in the treatment of sore throat ? Every doctor with a child of his own that has had an acute pharyngitis will know what a temptation it can be to give penicillin or one of the newer antibiotics; and will feel himself in sympathy with WHEATLEY,[3] who favours giving rather than withholding these agents Yet in this country four studies on the natural history and therapy of acute febrile sore throat—two in general practice [4 5] and two in military personnel [6 7]—do not on the whole support such a policy They show that the majority of such sore throats settle down, untreated, in a few days, that streptococci can be recovered from only about half to two-thirds of the patients, and that sore throat associated with β-hæmolytic streptococci cannot be reliably distinguished on clinical grounds alone from other sore throats Penicillin can shorten the illness a little but is really necessary, it seems, only for severe cases and those with such immediate complications as otitis media or sinusitis The compelling argument, in theory at any rate, for the "blanket" policy of treating all sore throats promptly with penicillin arises not from these considerations but from the danger of delayed non septic complications (rheumatic fever, nephritis), which can be prevented by adequate treatment of the preceding sore throat but once they have arisen are not susceptible to radical cure and may cause serious invalidism and shorten life Does this theory hold good in practice ? In over 400 cases of sore throat associated with β-hæmolytic streptococci that were seen in general practice,[4 5 8] or under similar conditions,[6 7] and that were not treated with penicillin, rheumatic fever ensued in not a single instance The mildness of such sore throats is confirmed by BRUMFITT and SLATER's[7] observation that only 17% of untreated cases of proved group A β-hæmolytic streptococcal infection showed a significant (two-tube) rise in antistreptolysin titre It is difficult not to conclude that penicillin is needed only for severe cases and those with septic complications But this conclusion seems to conflict with that of the American Heart Association, which has issued a report on this subject, from the point of view of preventing rheumatic fever and bacterial endocarditis,[9] compiled by a committee composed of experienced and authoritative workers

The report summarises the symptoms and signs of the typical case of streptococcal sore throat, which should be treated with penicillin "on sight", but many cases are not typical, and accordingly the committee suggests that throat-swabs should be cultured more extensively The prevention of rheumatic fever demands the eradication of streptococci from the throat—not just their suppression The bactericidal penicillin (rather than the bacteriostatic sulphonamides) is the drug of choice, with the less effective broad-spectrum antibiotics reserved for patients who are hypersensitive to penicillin Of the possible penicillin preparations, the committee favours administration of the injectable long-acting benzathine penicillin G, or procaine penicillin with aluminium monostearate in oil, for at least ten days Penicillin by mouth is also effective, but only if the patient cooperates, and thus the committee does not recommend this route The committee proposes that, where a previous history of rheumatic fever is clearly established, chemoprophylaxis should be given in all seasons throughout the rest of the patient's life, to prevent streptococcal reinfection For choice the committee would inject each month 1,200,000 units of benzathine penicillin G, or, *failing this, it would* give by mouth each day 1 g of sulphadiazine or 500,000 units of penicillin G

Outstanding work on the relation of group A β-hæmolytic streptococci to rheumatic fever has been done by the members of this committee, and particularly by RAMMELKAMP and his associates[9] at Fort Warren Consequently the American Heart Association has been campaigning widely for chemoprophylaxis to prevent rheumatic fever, and in the U S A some would now regard it as negligent not to give a patient known to have had rheumatic fever antibiotics continuously But many doctors would feel uneasy about the committee's recommendation—it might almost be termed a life sentence—that antibiotics should be administered throughout the lives of patients who have had rheumatic fever Furthermore many would demur at the committee's implied recommendation that all sore throats known or suspected to be due to group-A β-hæmolytic streptococci should be treated with antibiotics, at least until a throat swab has been cultured These policies are based on the following premises[10] firstly, that approximately 3% of hæmolytic streptococcal throat infections are followed by rheumatic fever, irrespective of the age of the patient, secondly, that rheumatic heart disease can be prevented by preventing first attacks and recurrences of rheumatic fever, and thirdly, that the benefits of life long chemoprophylaxis warrant its risks That rheumatic fever follows infection of the throat by a group A β hæmolytic streptococcus in a susceptible subject must now be taken as proved

[10] Mortimer E A, Rammelkamp, C H *Circulation*, 1956 14 1144

The statement that 3% of such infections will be followed by rheumatic fever rests mainly on the extensive work at Fort Warren, and it is not at all certain that conditions there reflect those in general practice

Fort Warren, an Air Force base and a reception centre for new recruits, receives a constant stream of young men. Epidemics of streptococcal disease have arisen when one of the new arrivals has been a carrier of virulent organisms. In a classical experiment the Fort Warren workers found that only 2 cases of rheumatic fever occurred in 1178 patients with acute streptococcal sore throat treated with depot penicillin whereas 28 cases occurred in 1168 untreated controls [11] Subsequent work with other forms of penicillin or other antibiotics gave much the same results.

Impressive and valuable as this work is, it is based mainly on epidemics of streptococcal infection in a highly selected population in specialised surroundings Its results cannot be applied directly to endemic sore throat seen in general practice without ignoring an important ecological difference BRUMFITT and SLATER [7] noted that there may be differences between epidemic and endemic streptococcal infections; and the Fort Warren group [12] have themselves reported changes in the virulence and infectivity of group-A β-hæmolytic streptococci associated with the chronic carrier state Nevertheless they believe that the apparent variation in the incidence of rheumatic fever with age or with geographical, seasonal, or economic factors, is secondary to the effect of these factors on the distribution of the streptococcus Where the spread of the organisms is made easier, rheumatic fever will be more common, but the proportion of streptococcal throat infections which are followed by rheumatic fever will remain 3% On the other hand, SASLAW and STREITFELD,[13] working in Miami, Florida, where rheumatic fever is uncommon, found that group-A β-hæmolytic streptococci could be isolated from the throats of a large number of school-children once or more often over several years About half of the positive throat swabs were associated with significant rises in the serum titre for antistreptolysin O, suggesting that a true infection (rather than commensalism) was present in at least half the cases From this they deduced that the expected number of cases of rheumatic fever in the population they were studying should have been 212, if the 3% figure were universal. In fact none were reported.

There can therefore be no hard-and-fast rule that 3% of streptococcal infections are followed by rheumatic fever BYWATERS [14] believes that the normal rheumatic-fever rate after sporadic streptococcal sore throats in school-children in the London area is about 0·1%, but the rate may rise to as much as 10% during epidemics Nor can one assume as does WHEATLEY, that the decline in the incidence of rheumatic fever and of streptococcal diseases generally is due to the more widespread use of antibiotics This decline started decades,[15] and possibly centuries, before the introduction of penicillin although doubtless the antibiotics have hastened it in recent years. Furthermore, the relation of rheumatic fever to rheumatic heart-disease may not be as close as is commonly thought It has been regularly found that only 40–60% of those with rheumatic heart-disease on clinical examination or at necropsy have a history of rheumatic fever or of chorea WILLIUS [16] could find no relationship between the number of attacks of rheumatic fever and the severity of the heart-disease judged by the duration of life It is probably true that, on the whole the more severe and numerous the attacks of rheumatic fever the greater the chance of severe rheumatic heart-disease but the correlation is not close WEINSTEIN et al [17] from a seven-year follow-up study of 167 cases of scarlet fever treated with penicillin, conclude that treatment may suppress the clinical manifestations of rheumatic fever but not the subsequent valvular deformities (This work has been criticised by MORTIMER and RAMMELKAMP [10] mainly on the score of internal inconsistency.) It would be ridiculous to suggest that rheumatic heart-disease is unrelated to rheumatic fever but clearly it would be equally wrong to assume that all rheumatic heart-disease would be prevented by abolishing overt rheumatic fever

In its recommendation for chemoprophylaxis of streptococcal infections in rheumatic subjects the American committee is not absolutely unyielding:

> "Although recurrent attacks of rheumatic fever occur at any age, the risk of recurrences decreases with the passage of years Some physicians may wish to make exceptions to instituting prophylaxis in certain of their adult patients particularly those without heart disease or who have had no rheumatic attacks for many years"

Some have found that a useful working rule is to continue chemoprophylaxis for five years after the last attack of rheumatic fever or until puberty, whichever is the longer period The risk of recurrence after this period is reduced, although it still remains Against this must be set the risks of continuous medication, which include sensitisation to antibiotics, the development of resistant organisms and (because of the intramuscular injections) enhanced severity, if not enhanced likelihood of poliomyelitis On the scale of a life-span chemotherapy may have other dangers of which we still know nothing long-continued administration of sulphonamides to rats and mice is associated with the development of cancer in strains of animals not normally susceptible to neoplasms and with the early onset of cancer in susceptible strains [18] The difficult, crucial experiment has not yet been done, and perhaps it cannot be done It would consist in a controlled trial of antibiotic treatment of sore throats as they present in general practice, with the results judged mainly by the subsequent development of rheumatic heart-disease Meanwhile, those who argue that all sore throats should be treated with antibiotics in order to prevent rheumatic heart-disease are relying on a chain of indirect evidence which is very suggestive but in which there are still serious gaps

The primary object in treating acute febrile sore throat in most patients in general practice is to alleviate the immediate illness Sore throats associated with fever and chills, nausea, headache, swollen glands in the neck, and, particularly in children, vomiting are likely to be streptococcal sore throats associated with cough hoarseness and sneezing are likely not to be streptococcal, but the distinction cannot be made with certainty A throat-swab should be taken if possible but the decision whether to administer an antibiotic must be made clinically, before the result of culture is known Exudate in the throat is not a reliable guide to the infecting organism, but it is a strong indication for swabbing because it may be diphtheritic There is little to gain from treating with antibiotics mild sporadic sore throats, even if streptococcal, but in nurseries, schools, and camps and barracks, where streptococcal infections may reach epidemic proportions, it is important to give effective antibiotic treatment as soon as possible to all with febrile sore throats, and if the epidemic threatens to become troublesome chemoprophylaxis should be considered for the whole group at risk Patients with a history of rheumatic fever or who come of rheumatic families, and those with signs of rheumatic heart-disease, must be specially protected In them, continuous prophylaxis is justified, and in addition upper-respiratory infections must be treated vigorously pending the result of a throat swab Of the various methods of treatment procaine penicillin G, at the rate of, say, a million units daily, is probably the surest and, if this treatment is going to be given, it must be continued for at least ten days A single monthly injection of benzathine penicillin G 1,200,000 units is a convenient but painful alternative which is favoured by the American workers Tablets of oral penicillin G are less effective because of irregular absorption, and the patient may forget to take his tablets Phenoxymethylpenicillin is still under trial, and is not yet to be recommended[19] There is little evidence that the various antiseptic lozenges, with or without local anæsthetics, now offered for sale do anything to influence the course of the disease or give more than moral comfort

Annotations

RADIATION AND LEUKÆMIA

When, in 1955, at the Government's request, the Medical Research Council appointed a committee to examine the hazards to man of nuclear and allied radiations, one of the things about which more information was urgently needed was the ultimate effect of small doses of radiation The reported increase in the incidence of leukæmia in patients who had been irradiated for ankylosing spondylitis seemed a fruitful line of inquiry, and Dr W M Court Brown and Dr Richard Doll were asked to undertake a more extensive investigation of such patients than had hitherto been attempted Their findings were summarised in the white paper published in June last year[1] and a fuller analysis of their results is published this week[2]

In the short space of nine months the records of over 13,000 patients from 81 radiotherapy centres in Britain were investigated, the patients were followed up, the radiation received by the bone marrow was estimated, and the doses given to each patient over the period of survival were assessed The investigation was planned to include all patients treated for ankylosing spondylitis by means of ionising radiations during the years 1935–54, and to study further those cases in which leukæmia, aplastic anæmia, or myelofibrosis had developed In all, 72 patients have been reported as having both ankylosing spondylitis and one of these conditions—49 in the study series of 13,352 and 23 outside the series (including 8 not known to have had previous radiotherapy for their spondylitis) From national vital statistics, the numbers of deaths which would have been expected in the study series by Dec 31, 1955, were put at 2 9 for leukæmia and 0 3 for aplastic anæmia in fact, 28 deaths in the series were certified as attributable to leukæmia and 12 to aplastic anæmia Thus, the mortality from leukæmia among patients treated with X rays for ankylosing spondylitis was about ten times greater than the mortality in a normal population of the same age and sex distribution

A possible explanation is that patients with ankylosing spondylitis are more likely to get leukæmia than healthy people, irrespective of how they are treated Three findings, however, are against this Firstly, the distribution of the different cell types of leukæmia in irradiated cases was not the same as in untreated cases (the irradiation group contained a smaller proportion of lymphatic leukæmias) But this observation is based on the Registrar General's figures for cell types, which may reflect differing views on cytological classification Secondly, Abbatt and Lea's comparison[3] between irradiated and non-irradiated spondylitic patients suggested that there was no important association between leukæmia and ankylosing spondylitis irrespective of treatment Thirdly, a relationship has been demonstrated between radiation dose and incidence of leukæmia, and Court Brown and Doll hold that this is strong evidence that radiation plays a part in the causation of leukæmia, though it is conceivable that the liability to leukæmia varies among spondylitics in proportion to the severity of their disease

What is the nature of this relationship between dose and response ? An unequivocal answer to this question would have resolved many of the doubts concerning radiation hazards, but unhappily no clear cut solution has emerged, despite the most painstaking analysis of the known facts by Court Brown and Doll and those who helped them Their inquiry did not establish whether leukæmia could be produced by doses of radiation less than those commonly given in the treatment of ankylosing spondylitis Few patients received a mean spinal marrow dose of less than 250r, and the results give no direct evidence on the effect of doses of this order If the dose response relationship is curvilinear, a threshold may exist below which there would be no increase in the incidence of leukæmia Thus, small doses, such as those involved in diagnostic exposures, would not induce leukæmia Court Brown and Doll believe, however, that it is more reasonable to adopt the working hypothesis that there is no threshold dose They base this view on the linear relationship observed with the doses given to patients receiving only spinal radiation, and on the fact that when the mean spinal dose to the whole population of patients is considered the incidence also increases approximately in proportion to the dose at all but the highest levels If there is no threshold for the induction of leukæmia the situation is analogous to the induction of gene mutations by radiation, and the rate at which the dose is accumulated may not affect the proportional relationship Court Brown and Doll remark on the importance of using this quantitative relationship in as many ways as possible to test the "no threshold" hypothesis, and they refer to the findings of Stewart et al[4] which suggested that the risk of leukæmia may be greater in children who were exposed to diagnostic X rays in utero Discussing the leukæmia rate among survivors of the Hiroshima explosion, Court Brown and Doll conclude that, within the necessary limitations of the available data, the incidence is compatible with a linear relationship

[4] Stewart A Webb J Giles D, Hewitt D *Ibid*, p 447

One important implication of the no-threshold hypothesis is that any exposure to radiation over and above natural background, however small, must increase the risk of leukæmia, and it must therefore be supposed that some leukæmias have been induced by diagnostic irradiation, which, it has been variously estimated, in countries where radiodiagnosis is widely used, can add to the population gonad dose from 10 to 70% of the dose due to background radiation Similarly, fallout from nuclear explosions would be expected to add a smaller quota to the leukæmia figures As Court-Brown and Doll emphasise, however, this is not the only hypothesis which is compatible with the data Much more work must be done before the true dose response relationship is clear Indeed, inquiries of this pattern may not be capable of producing a firm answer, and investigations on a gigantic scale may be needed[5] The formidable amount of time and effort that must probably be expended to identify beyond doubt the effects of low doses of radiation are leading some people to wonder whether a nearer target should be the immediate aim It may be better to decide, as far as the present incomplete evidence permits, what is an acceptable risk to balance against the benefits of useful radiation, and then to do everything that can be done to reduce additional exposure from all sources to the "safe" level To wait until the dose-response relationship is fully explained may be to wait too long

THE WELLCOME TRUST

THIS is an age of trusts, if not of trust, but among the many and diverse bodies which support scientific research the Wellcome Trust is believed to be alone in drawing its income from a pharmaceutical business in which the trustees hold all the share capital This unusual situation has been created by the will of an unusual man Sir Henry Wellcome was the sole proprietor and autocratic director of the pharmaceutical manufacturing firm of Burroughs Wellcome & Co He was also a man of wide and discerning scientific interests, and the success of his business enabled him to support research to an extent probably unequalled by any other private citizen At first the laboratories, museums, and libraries which bore his name and drew on his purse were the private hobbies of the owner rather than part of a large commercial undertaking But in 1924, for administrative convenience, Sir Henry gathered them and his commercial interests together to form the Wellcome Foundation Ltd On his death all the shares in the Foundation passed to the Wellcome Trust The first five trustees[6] were nominated in his will, and they were charged to use the large and continuing residue of his estate to advance research The objects for which they were empowered to use the funds, though wide, were carefully set out in the will The emphasis was, naturally enough, on the subjects which specially interested Sir Henry, including pharmacy and pharmacology, tropical and veterinary medicine, and the history of medicine The trustees have no mandate to assist undergraduate or postgraduate education or to provide facilities for treatment

The first report[7] of the trustees nominally covers twenty years, but in fact ten anxious and strenuous years were spent in winding up a complicated estate, finding the funds to meet the heavy death duties, and setting in order the affairs of the Foundation on whose dividends the income of the Trust depends Even in these early years, which were further complicated by the difficulties attendant on a major war, the trustees found money and energy to support Dr Henry Foy's work on malaria and sickle cell anæmia in Greece and in Africa and to provide funds for the plant which supplied plasma and serum for all the civilian and most of the Service needs in this country from 1943 to 1945 Hard on these tentative beginnings they record the endowment of research chairs of clinical tropical medicine and of pharmacology in the University of London, and chairs of anæsthetics in McGill University and in the University of Pennsylvania Research fellowships to the value of £28,000 have been awarded through the Animal Health Trust and the Pharmaceutical Society, and the trustees themselves have spent some £15,000 on what they candidly describe as "unsystematic" awards mostly in biochemistry In 1955 they also introduced travel grants, including short-term grants for senior workers who wished to visit centres abroad for purposes connected with their researches The total benefaction of the Trust in the period covered by this report amounted to £1,170,164

Though the trustees have rightly put people before things, they have also provided some very expensive tools on permanent loan Electron microscopes have been bought for the Medical Research Council, for the University of Oxford, and for the University of Cambridge, which is also to receive a nuclear magnetic resonance spectrometer The libraries and museums of the three Royal Colleges in London and the Royal Society of Medicine are all receiving, or have received, substantial help, and many scholars and publishers have been enabled to print contributions to medical history One of the most important of these is the collected edition of Ehrlich's work

So far most of the Trust's benefactions have been made within this country, but the trustees are mindful that they are legally subject to no territorial limitations and that they draw their income from a world-wide trading organisation They are glad that they have lately been able to endow research posts in Canada and in the United States, the country of Henry Wellcome's birth

FOUL FOWL

APPARENTLY about two cases of psittacosis are recognised each week in England and Wales (The name "psittacosis" is used here without prejudice to cover all human infections due to this group of viruses which are not lymphogranuloma inguinale) This number is almost surely an underestimate, for the apparent geographical distribution of the disease seems to be related to the location of laboratories able to make the specific diagnosis About half the patients with psittacosis give a history of contact with budgerigars or other parrots, but there are three reasons for doubting whether this observation is of great importance In the first place these pets are far commoner than they used to be, and statistically their association with human infection may by now be negligible (Observations on the number of houses with budgerigars would be useful) Secondly, hens, ducks, turkeys, seafowl, various passerines, and pigeons have all been found to be infected and a few of these have been convicted of causing infection in man Lastly, it is common experience that some patients with psittacosis have had no traceable contact with birds of any kind

It has been thought that man is usually infected by inhaling feather dust or dried excreta. Except for finches and canaries (which are susceptible to infection) only psittacine birds share man's living-rooms in this country Nevertheless the amount of dust inhaled by the most ardent fancier and his family must be a trifle compared with that in the respiratory tract of a man cleaning out a chicken-house Infection in hens is probably rare Because of their numbers and semi domestic habits, pigeons have been suspected of causing some of the infections which cannot be traced to parrots Half the pigeons in Oslo show antibodies to psittacosis,[1] and figures of this order have been found in other towns This line of inquiry is worth pursuing and should be extended to pigeons kept for racing

[7] Wellcome Trust First report 1937–56 52, Queen Anne Street, London, W 1

When first seen in this country about 1930, psittacosis was a virulent disease apparently derived from newly imported parrots Importation was very soon forbidden, and thereafter the type of infection was on the whole less severe The disease had probably been present for many years but had remained undiagnosed until the severe infections called attention to its presence and provided material for specific diagnosis At the request of the pet trade, and because infection had by then been recognised in other birds, the ban on imported parrots was lifted in 1952—an act of administrative daring which was followed almost at once by several outbreaks of severe infections traced to imported parrots The ban was reimposed This experience suggests that the strain of virus current in South America (whence come most of these birds) may be more virulent for man than that endemic here, but we know of no experimental support for this idea That the more virulent strain has not become established is perhaps due to the fact that it is even more fatal for birds than for man

Psittacosis is not a grave danger to the public health, and treatment with some of the newer antibiotics has been successful, but it can be an alarming and distressing disease In our present state of ignorance prevention will not be easy Active immunisation is possible, but few except bird-fanciers are likely to ask for it Without examples plain to see it would be hard to persuade the public that any harm can come from a bird so elegant and amusing as the little parrots If pigeons spread the disease this will be one more reason for reducing their numbers, but so far they seem to have defied all methods designed for their annihilation in town and country Before we are compassed about with any more restrictions and prohibitions it would be wise to try to establish beyond doubt the source of the two infections which are detected each week

PLASMA-INSULIN ASSAYS

INSULIN-RESISTANCE has rather more possible causes than diabetes itself Resistance may be noted during diabetic ketosis or (in the absence of ketosis) in association with allergic manifestations or immune reactions, infections, non-ketotic acidosis, and endocrinopathies such as Cushing's syndrome and acromegaly Resistance to exogenous insulin may also be found in non diabetics, such as mentally ill patients given insulin shock treatment The mechanism of resistance in any one case is often hard to understand and to investigate, though there have been notable recent advances in laboratory techniques to apply to this problem We reviewed the immunological approach last year,[2] and the paper by Dr Baird and Dr Bornstein on p 1111 of this issue represents the most recent advance in the technique of measuring "insulin activity" and insulin antagonists in the plasma The presence of such antagonists in the plasma has been inferred ever since it became known that, after pancreatectomy, patients needed no more than 30–50 units of insulin a day to control their diabetes,[3] though the insulin requirement of many "ordinary" diabetics is much greater than this

The nature of these insulin antagonists has not been established, but it is apparent that they are of more types than one, some have a very protracted effect,[4] and (as Dr Baird and Dr Bornstein found) some are stable to heat and to extraction procedures, whereas others are labile to such procedures Their presence in plasma has greatly complicated the task of measuring insulin levels in blood, for it is a resultant of the action of insulin and of insulin antagonists that is measured by the two main methods of insulin assay—the rat hemidiaphragm method, in which glucose utilisation[5] or glycogen deposition [6] is measured in vitro, and the method of following the change in the blood sugar of alloxan diabetic, hypophysectomised, adrenalectomised rats after they have received injections of standard doses of insulin or of a test plasma [7] Such rats have proved too fickle for satisfactory insulin bioassays, and most effort is now being expended on the rat hemidiaphragm method Stadie et al [8] used this method and radioactive insulin to study insulin binding They found that insulin, labelled with either ^{131}I or ^{35}S, was firmly fixed by rat diaphragm after a short exposure, and despite many subsequent washings, and that the activity of the bound insulin was affected by other hormones such as those of the anterior pituitary [9] Accordingly isotopes were used to differentiate an effect on insulin-binding from one on the hypoglycæmic action of insulin In the application of the rat diaphragm method to assays of "insulin" in blood, there is good evidence that insulin is indeed being measured, but the evidence cannot be accepted as conclusive, in view of Randle's[10] work showing the effect of growth hormone on this system Groen et al [5] have shown that in dogs the "plasma-insulin" activity disappears after pancreatectomy, and that cysteine and glutathione, which inactivate insulin, also inactivate the hypoglycæmic material in plasma At least two proved cases of β cell tumours of the pancreas have been shown to have high "plasma insulin" activity,[5 11] and an increase in the "plasma insulin" of a normal fasting man has been measured in blood withdrawn a few minutes after insulin had been administered [12]

Baird and Bornstein now report a real advance in their work *on the separation of the* "insulin" fraction of plasma from the insulin antagonistic one by extraction By their results in patients they have confirmed the separation of diabetics into those with available plasma insulin and those without (the juvenile diabetics)[4] Plasma extract from a woman aged 29 who was admitted to hospital in diabetic coma had insulin activity, but this was masked in the whole plasma by an insulin antagonist demonstrated in the residue of the extraction procedure Such masking of insulin activity in the plasma by inhibitor substances was demonstrated in 3 other patients with diabetic ketosis, and confirms the findings of two other groups of workers [11 13] Baird and Bornstein's results in normal non diabetic persons indicate that even in them there is a balance in the crude plasma between the effects of insulin and those of its antagonists A relative excess of the antagonists, whatever they may be, could account for the high insulin requirement of some non ketotic diabetics

DR A G MAITLAND-JONES, consulting physician to the children's department of the London Hospital, has lost his life while fishing on the river Usk

Reconstruction

CONSULTANTS AND SENIOR REGISTRARS
THE PRESENT AND THE FUTURE

THE number and distribution of consultants is causing anxious questions in the minds of medical administrators, whose quite recent assessments of needs have been confounded by the rapid but uneven march of medical progress, of some of the consultants themselves, who are in danger of being under-employed because of this progress, of S H M O s whose claim to better status is once more under review, and of senior registrars, whose difficulties in making the leap into consultant status are well known

How effectively, in fact, are the specialist services meeting needs, and should these services be substantially expanded or modified to meet today's demands, which differ from those of even a decade ago? Inquiry in various hospital regions suggests that there are more or less enough beds for the acute sick, though the beds are not always in the place, or in the specialty, where they are needed, that patients found to need immediate inpatient treatment receive this without delay, and that the delay in seeing *new outpatients* is causing more concern than the delay in securing their admission There seems at present to be no prospect of the appointment of many additional consultants, but the argument for recognising a new grade of "specialists" is increasingly difficult to refute

Hospital Buildings and Beds

If it is true that there are more or less enough beds for the acute sick,[1] two important reservations must be made The first is that out-of date hospital buildings must be replaced and the second that beds must be redistributed in the places and the specialties where the need is greatest

Buildings

With the long continued restriction on capital expenditure, some hospitals in which the acute sick are treated (and which even in 1939 were unfit for this purpose) have never been brought up to date These hospitals, which include some former poor-law institutions, urgently need to be partly or completely replaced Roughly speaking from scratch a new "acute" hospital can nowadays be built at a cost of £5000 a bed, and a new block at a cost of £3000 a bed, but an outdated building can often be made serviceable for some years at a cost of about £1000 a bed The price of putting up a new block represents only four years maintenance costs at £15 a bed per week, and, on the ground that we must spend more in order to spend less it seems clear that an extensive building programme should no longer be delayed The provision of suitable modern buildings bears closely on the number of consultants who can usefully be employed, for the appointment of additional consultants is commonly prevented by the lack in old buildings, of physical resources (operating-theatres pathology laboratories), and the consultant establishments cannot everywhere be brought up to the required level until these capital developments have been made

Redistribution of Beds

In almost every region hospital beds are not distributed in accordance with present day needs Often, owing partly to the dual origin of our hospitals, beds are too scattered (in one medium-sized town in the North a physician has beds in four different hospitals) beds may not be in the places where they are most needed (namely the new towns and the towns which have grown most extensively), and beds are not always distributed between specialties according to demand In the past ten years the pressure on beds for the tuberculous has declined sharply, and that on beds for patients with infectious diseases has continued to fall, and there is now much less call than formerly on beds for children These changes are not yet fully reflected in the division of beds between the different departments

The Consultant's Work

Several ill-defined factors govern the amount of work a consultant can undertake, and the sufficiency of establishments can be gauged by no single test

A consultant with a maximum part-time contract may put in 40 hours' work a week instead of his agreed 31½, and a review in one region has shown that some 90% of consultants do in fact work substantially longer than their contract requires Such people get through *more* work *than their* agreed *number of sessions* would suggest Then again, the amount of work that can be done depends on distances to be travelled and the number of hospitals to be visited, on cooperation with colleagues and help from registrars and on associated activities (a consultant on a regional board or management committee may need extra help during his tenure)

Beds

For a physician or surgeon working maximum part-time, a convenient dividing-line is the 40-bed mark, with, say three outpatient sessions a week By this far from accurate criterion, it seems that not many in the South are overburdened A few have substantially more than 40 beds, but these had such a number before the start of the service and, being well supported by registrars, are reluctant to forgo any now *In the North on the other* hand, it is commoner for clinicians to have beds in excess of 40 But here as in the South, there is no opening for many new appointments if new consultants are to have charge of as many beds as do their established colleagues

Waiting-lists

The extent to which a consultant is meeting the demand on him is commonly measured by the waiting list Yet a waiting-list is a worthless guide without knowledge of the hospital and the consultant

In one hospital a waiting list may be regarded as a disgrace, and its surgeon may almost abolish his list by making full use of the operating-theatres in outlying hospitals and (if a spirit of coöperation prevails) by borrowing beds from his colleagues and holding evening operating sessions His colleague up the road on the other hand, may all the time be adding diligently to his waiting-list in order to underline his claim for extra help At one hospital no patient's name may be put on the waiting list unless there is a reasonable chance of his being admitted within a couple of months, at its neighbour names may be entered on the list without regard for the likelihood of the patient being sent for in the next few years Hospitals with long waiting lists might have still longer ones if general practitioners had not wearied of seeing their patients wait and so begun to send new cases elsewhere Most waiting lists are inflated by perhaps 20-25%, and a further 10% or so of patients may be expected to refuse admission when the time comes[2] Nevertheless when full account is taken of local conditions as in the careful study by Professor Grundy and his colleagues[2] waiting-lists are useful indicators

Grundy et al found that in Cardiff at the end of 1954 four departments accounted for 93% of the patients who had waited two years for admission These departments were orthopædics, gynæcology, general surgery, and urology In other regions, too these departments together with those of the other "regional" specialties (plastic surgery, neurosurgery) have long lists, and it will be noted that each of these specialties requires an operating theatre The lists tend on the whole to be longer in the north than in the south of England In the larger specialties, except possibly orthopædic surgery and gynæcology, the lists are beginning to come down, and there is no delay in admitting patients who are in pressing need of treatment But the delay suffered by the remainder, although it may not threaten lives, may prevent the patients from working fully and cause distress Grundy et al, for instance, found that in a group of patients who were interviewed at home and most of whom had been over a year on a waiting-list, 21% had a medico social problem associated with the waiting period

---

[1] See Studies in the Functions and Design of Hospitals London 1955 p 149

[2] A Study of Hospital Waiting Lists in Cardiff a report prepared for the board of governors of the United Cardiff Hospitals By F GRUNDY R A N HITCHENS and E LEWIS FANING

Outpatients

The pressure on outpatient departments continues to grow at much the same rate, partly no doubt owing to the growing resources for treating patients without admission to hospital,[3] and partly owing to the ever-increasing complexity of medical practice which calls more and more often for reference to hospital In the outpatient department clinicians are heavily weighed down—including those (such as many physicians) who have no great cares with their waiting list One physician in the Midlands owns regretfully that, despite his best endeavours, new patients rated by their doctors as urgent cases must wait for 3 weeks before their appointment falls due, while the remainder must wait 16 weeks Delay, though often less severe, seems to be the rule in nearly every other clinical field, and is causing more general concern than delays in admission from the waiting-list

Openings for Consultants

Senior registrars in general medicine, general surgery, and obstetrics and gynæcology are having the utmost difficulty in securing a consultant post, because vacancies are few For a consultant appointment in medicine 50 or 60 candidates may apply, for one in surgery 45 or 50, and for one in obstetrics and gynæcology 35 or 40 Competition is fierce in some of the smaller specialties, such as orthopædic surgery, plastic surgery, and neurosurgery, but it is never as massive as in the three main fields

The number of senior registrars who have completed four years' training varies greatly between different regions Whereas in some regions there are none or hardly any, in at least one there are a dozen in the three main branches (general medicine, general surgery, and obstetrics) to say nothing of the people who are holding research posts but hope to get consultant appointments later In one region it has been suggested that the senior registrars should be dismissed on the grounds that the younger generation, trained since 1945, can no longer be denied their opportunity, and that the remaining older men are never likely to secure a consultant post since they have applied again and again without being short-listed more than once or twice This does not exclude the possibility that such men are good enough to become consultants it simply suggests that, against the weight of exceptional competition, they may not gain advancement

Indeed what evidence there is suggests that the majority of these doctors are fully fit to be consultants In the region with a dozen who have passed the four-year mark a committee was set up to examine dispassionately their claims to a consultant's competence This committee, working with the help of senior university teachers, each of whom has a very high standard, found that anyhow ten of the twelve are suitable for a consultant post

Replacement

In the three main fields the openings consequent on death or retirement may be even fewer in the coming years than published figures[4] indicate, for, as the demand on some of the other specialties shrinks, their exponents will tend to revert to the main fields The specialist in tuberculosis is turning to other diseases of the chest, thus diminishing the calls on the general physician, and specialists in infectious diseases and venereal diseases, in which the work has decreased, may go back to general medicine To a lesser extent the same process may declare itself in surgery For instance, owing to the decline in tuberculosis, some thoracic surgeons are now more lightly employed, and, since the transition to cardiac surgery is sometimes denied to them they are tending to turn (quite gladly in the case of the older men, who received a general training) to general surgery

Expansion

Expansion offers slight but ill defined hopes Some regions, including a few which started with a good complement of consultants, increased the number of these rapidly after the appointed day, and now they need no more than one or two in each of the main field At the other extreme is a region which began with too few consultants and is still seeking to expand their numbers at the rate of about twelve a year—though it does not always succeed in this

The speed of expansion is regulated by four principal factors physical resources, the Ministry of Health, money, and the availability of suitable candidates

Physical resources —Obviously it is no use appointing a surgeon who will have no operating theatre, a physician who will have no outpatient facilities, or a pathologist who will have no laboratory At a rough estimate, it seems that about half the planned increase in consultants is held up by lack of such resources

Ministry of Health —The proposal for each new post has to be approved by a Ministry of Health committee, which includes representatives of the Joint Consultants Committee This seems to exercise its powers temperately in order to secure not only a sound use of money but also the best distribution of scarce skills thus an application from a regional board in the south of England for an additional radiologist may be refused on the ground that the North has a greater need of radiologists, who will not go there if they have the option of settling in the South But the committee cannot be acquitted of unwisdom at least two boards have been told that their proposal to set up a new post was turned down because the board would be unable to find a suitable person to fill it—an affront to the board's ability to decide when to leave a post unfilled

Money —The experience with money differs between different parts of the country In one region the need is mainly for consultants in specialties where candidates are few and not always good, and the board has decided not to allocate more money to make additional appointments until the quality of candidates improves In another region, where the number of consultants is growing year by year, money seems to be no serious obstacle In a third region money seems to be a very real obstacle

A board budgets for increased consultant staff by including the cost under developments in its revenue estimate A board that is granted less money under this heading than it has applied for must decide which development to forgo and in this one region where money is a main difficulty it is thought that expansion might proceed more certainly if the estimate for consultants formed a separate category from which the money could not be transferred to another heading

The candidates —Candidates are few and opportunities relatively many in anæsthetics, psychiatry, radiology, otology, ophthalmology, and to a lesser extent pathology, and the prospects seem bright, too, for the medical fearing the effects of repression had permitted them to smoke.

[4] Consultant and other specialist staff in hospitals See *Lancet* April 13 1957, p 785

Smoking Forbidden at School.—In only 5 schools was smoking forbidden. In 1, boys were caned if caught smoking—the youngest offender was aged 12. Several headmasters pointed out that smoking is very common in the teaching profession, and one remarked that boys have only to see the rush for pipes and cigarettes in "break" to realise that their masters do not seem to take much notice of warnings. Masters, like parents, may feel diffident about enforcing the rule. One headmaster had recently given up smoking to convince a boy in the VIth form that this could be done, but it had little effect on the boy.

Combating the Habit.—44 headmasters were in favour of giving factual information to boys on the ill effects of smoking, 7 were doubtful, and 3 were against it. In one school the doctor saw all the boys at least in their first and fourth years (ages 12 and 15) and spoke to them about the ills of smoking. In another school the Vth form boys suggested that advice should be given before 13, when many boys start smoking. It may be difficult to convince boys that the danger is personal and not remote in time, and any semblance of tendentious propaganda in its presentation must be avoided. One headmaster who is against this teaching said that many VIth form boys are willing to consider objectively problems of modern life, but few base their personal conduct on purely intellectual evidence. Another thought it unnecessary because in his experience smoking has been uncommon among boys for some years, but he was unique in this view. Those who doubted the value of instruction held that because of the example set by adults it is hard to influence the adolescent, more could be done by informal conversation between masters and boys, and the basic safeguard is stricter parental control and a more rigid enforcement of the law about the sale of tobacco. Several headmasters pointed out lectures by outside visitors could carry more conviction than advice from masters who are smokers.

BOYS' PUBLIC SCHOOLS

The replies from the headmasters gave the impression on the whole, that addiction to smoking is less serious in public schools though in one, where boys are punished if caught smoking, it is common outside the surveillance of the school. The age at starting is later—often 14–15—and many boys do not smoke at all until they have left school at 18. One headmaster said that on the whole there is less smoking by people in their teens now than ten years ago. In one school the boys are permitted to smoke under certain conditions, and probably not half of them do so. One headmaster said that the habit is formed at home during the holidays.

In one school of 640 boys, of whom 350 were over 16, about 6 smoked habitually before 17 and not many more between 17 and 18. At another school about two thirds smoked and had begun at 13½ on the average. One headmaster pointed out that few of the boys leaving for universities smoked.

Of 19 headmasters 12 were in favour of giving factual information to boys, 3 thought it would be of doubtful value, and 1 was not in favour. At one school two thirds of 70 boys leaving school thought instruction should be given at an early age before smoking is begun.

GIRLS' PUBLIC SCHOOLS

Replies from the headmistresses of 3 public schools suggested that the problem does not exist in these schools. As one said, "it is no longer considered clever to smoke."

I wish to thank the Marie Curie Memorial Foundation for permission to study and publish this information, and the headmasters and headmistresses for their help.

CENTRAL HEALTH SERVICES COUNCIL

EARLY last year the Minister of Health asked the Council's Standing Medical Advisory Committee[1] for guidance about the present need for welfare food supplements other than milk to the diet of expectant and nursing mothers and young children under 5. Requirements of vitamin D and the supply of orange juice to children between 2 and 5 were two points on which the Minister was particularly anxious for advice. Changes in the availability of foodstuffs as well as dietary studies in recent years had suggested that it might no longer be necessary to continue these supplements.

A subcommittee formed jointly with the Scottish Standing Medical Advisory Committee began to review this subject a year ago, and its final report is expected soon. An interim report showed that most of its members agreed with the conclusions reached by the British Pædiatric Association in 1952 that children between 2 and 5 received adequate amounts of vitamin C from a mixed diet and that the issue of orange juice should be restricted to children under 2. But a minority of the subcommittee thought that there were still circumstances where this supplement was called for and that it should continue. Additional information was being sought and a further report would be prepared.

Another interim report concerned the content of vitamin D in welfare foods. The subcommittee's view was that the present level of fortification should be reduced so as to minimise the risk of causing hypercalcæmia while still continuing to give protection against rickets. A reduced level of fortification was recommended for infant cereals, so that a child of 9 months taking the recommended amount of a cereal would receive therefrom 200–400 international units of vitamin D daily. Assuming that these recommendations were implemented, the subcommittee further advised that National cod-liver oil should contain an average of 100 I.U. per g. and National dried milk an average of 90–100 I.U. per dry oz. (In 1953 the Ministry of Food recommended manufacturers of National dried milk to add 500 I.U. of vitamin D, as calciferol per dry oz., so as to allow for a maximum deterioration of 44%, thus giving a minimum of 280 I.U. per dry oz. in the food as marketed.[2]) Consultations have begun between the Ministry of Health and the Ministry of Agriculture Fisheries and Food with a view to bringing the subcommittee's recommendations about vitamin D into effect.

In 1955 a subcommittee of the Standing Mental Health Advisory Committee began a review of the functions of the various authorities concerned with arrangements for the treatment and care of persons suffering from mental illness at all ages or from infirmity arising from old age, and the results of this inquiry are summarised in the council's report. The subcommittee saw need for a closer coordination between the authorities concerned, especially between individual workers, and referred particularly to the schemes at Oldham and Nottingham. Dealing with alternatives to treatment in mental hospitals, it suggested that if there were more health visitors, district nurses, home helps, and social workers to give domiciliary help and closer coöperation with general practitioners, many patients could be retained in the community. The public should be made more aware of the psychological problems arising from the increasing number of old people in the community who need help. While local authorities should take the lead in this matter, their health visitors and social workers needed the active cooperation of other persons and bodies in close touch with families and able to assist in the home care of the aged who have physical and psychiatric disabilities

The Minister has accepted the advice of the council that no action should be taken on these recommendations pending the report of the Royal Commission on the law relating to mental illness and mental deficiency

GENERAL MEDICAL COUNCIL

IN his address to the council's 194th session on May 28, the president, Sir DAVID CAMPBELL, discussed the relations of Great Britain to other Commonwealth countries in the sphere of medical education and registration The General Medical Council, which in the autumn of next year would celebrate its centenary, had been the model for and indeed the mother of all the medical councils in the Commonwealth The statutes establishing them had been based on and have often copied verbatim the words of the British Medical Acts Their procedure followed our own closely, not only on educational but on ethical matters Sir David spoke of his recent visits to Uganda, South Africa, Malaya, and Hong-Kong The council while seeking to maintain a high standard of medical education, had always been ready to encourage new medical schools overseas by visitation and advice, and might sometimes perhaps have taken a temporary risk in granting recognition But the risk, if it existed at all, had always been well worth while It had led in every case to a striking improvement in the provision of facilities for education and in the standard of attainment There was more to be done, Sir David declared The council had by statute no responsibility for post graduate education Yet the position of the specialist staff in some of the countries he had recently visited was such that, though there were men holding senior medical posts in the medical services, there was a striking gap between them and the junior staff It was imperative, if the medical service in these countries was to develop on modern lines, that the gap should be filled by doctors trained locally as specialists in medicine, surgery, and midwifery, yet willing to submit themselves to any standard of examination demanded in this country And they were desperately anxious to do so On the basis of what he had seen, it would be a good thing, therefore, for this country and for the Commonwealth if bodies which grant higher qualifications were to follow the example of the General Medical Council and approve the medical schools of the Commonwealth countries with whom we had reciprocity as places where the candidates for their examinations could be trained

More than six years had passed, Sir David remarked, since the publication of the reports of the eight committees on medical auxiliaries appointed in 1949 under the chairmanship of Mr Zachary Cope The recommendations of the committees had been discussed by the Health Departments with interested bodies, and last October the Minister and Secretary of State issued a memorandum containing details of a provisional scheme for the statutory registration of chiropodists, dietitians, medical laboratory technicians, occupational therapists, physiotherapists, radiographers, remedial gymnasts, and speech therapists collectively referred to as " professions supplementary to medicine " It was proposed that the machinery should consist of a separate registration board for each of the "supplementary professions" and a coordinating council Observations on these proposals had been invited from many bodies, including the General Medical Council Proposals put forward at earlier stages had been considered at the time by the executive committee on behalf of the council and the committee had then made certain suggestions Since the new proposals appeared to cover the points made by the committee, it had not been thought necessary to offer any further observations

In England Now

A Running Commentary by Peripatetic Correspondents

MY mind was switched from Africa to a Surrey village by the remark of a speaker at a recent conference that the principle of Occam's razor did not apply to practice among African children, until at least three distinct diseases had been diagnosed in each child, one had hardly started On Thursday afternoons, which was his "no surgery" evening, my father used to take me on expeditions which sometimes finished up with a splendid tea at the Hautboy at Ockham, where William of Occam was born late in the 13th century On one occasion, after animadverting on the charge of a shilling a head—ninepence he thought would have been more appropriate for a tea which included cakes and what we called "real" strawberry jam—he told me about William and the follies of the schoolmen and the early monkish scientists I grew up with a picture of a man in a grey habit plucking out a hair and attempting to split it with a "cut throat" like the one my father used each morning, while his colleagues peered down primitive microscopes trying to count the number of angels dancing on the point of a needle

By the way, the *Oxford English Dictionary* has blunted the razor (why razor? because it cut away the undergrowth?) which it describes as the principle that "things not known to exist should not, unless it is absolutely necessary, be postulated as existing" The original instrument of Old Bill Occam—*Doctor invincibilis et venerabilis Inceptor*—had a keener edge—*Entia non sunt multiplicanda praeter necessitatem* Six words instead of sixteen

* * *

The need for reform of the English language had never struck me with much force till Bill (now 5) started to read and write Like all children, he is essentially logical He spells as he hears, and darned good spelling it is *too*, much better than *ours*

We have a game that whiles away the tedious hours before the blessed release of bedtime I write down a series of words for him to read, usually making some sense, such as HOCKEY MAN HIT DADDY POOR LEG Then it's his turn, and he writes words for me to read Alas, my sense of logic has been so warped through the years that often I can't RASING KRRE (racing car) FAYS (face), PYLO (pillow), RABYT (rabbit) O K so far perhaps But what *about* SCRYRAL which turned out to be squirrel, and MYRA (mirror), and UGCL (uncle), not to mention FROT (I bet even the otorhinolaryngologists didn't recognise that one) He writes DJ for J as in DJI FI (and he's right of course) The usual nursery class spelling for train is CHRAN, and RALRA is his interpretation of railway With DRORYNGE he strikes a pleasantly medieval note, but at HRISI for Horsey I decided he'd given up trying, even I don't pronounce it that way

I am reluctant to pervert such admirably accurate descriptions of what he hears Surely *to do so* would discourage the developing scientific mind? Perhaps everyone would benefit from Speling Reform Kood it be that behaivyer dissorders arise sumtimes from speling tenshuns? Is the increase in neuroses, gastric ulcers, cardiovascular disease, &c, directly related to our higher and higher standards of literacy? There is a good case for another Royal Commission, and I hope that Her Majesty's advisers will have the sense to appoint Bill as chairman

* * *

Post-war travel started in earnest in 1947 and many a traveller, like myself, must *be renewing* his passport this year To me mine is a valuable document, of historical as well as of geographical interest

The first year I had it I went to America, the land of freedom and of vigilance My finger prints were taken before a visa was issued which cost $2 Those were the days when dollars were beginning to be precious, yet I got £500 worth for seventy days Yet another testimonial to American hospitality is that I used less than half I was advised to transfer the rest into dollars and then buy pounds back and make a big profit but I have always prided myself that I did not Formalities such as declaring I had not earned money and therefore was not owing income-tax had to be gone through before I could leave.

The next year, I went to Germany and had to have a special permit to visit the British military zone I went via the Hook and thence to Cologne Sept 5, 1948, the date of my passage through Holland did not mean much to me when I landed, but I soon discovered that the decorations all over the country were in honour of the golden jubilee of Queen Wilhelmina The German currency had been revised shortly before and the British non-smoker like myself could no longer win himself a welcome with cigarettes Money apparently presented no difficulties on the Continent until 1950, and as I sometimes took my wife and three children, I was often glad of the limit

I strongly dislike visas and cannot help feeling that countries like Finland could well dispense with them, for the 450 Finn marks (about 10*s*) is hardly worth the trouble of collection The stamps on my passport are surprisingly few, a 82 stamp, three Finnish stamps of 300, 100, and 50 marks and some Spanish ones, some stuck on top of the others My passport shows that Germany, the three Scandinavian countries, Holland, Italy, Switzerland, and France responded to the Foreign Secretary s plea "We request and require in the Name of His Majesty all those whom it may concern to allow the bearer to pass freely without let or hindrance and to afford him every assistance and protection of which he may stand in need " Her Majesty makes the same plea

* * *

Though my researches are not exhaustive, I have so far seen only two medical journals in which a substantial bulk of the reading matter consists of letters to the editor They are both weeklies published in London W.C Why, one wonders do so few doctors in the United States think it worth while writing to the *J.A M.A* and are there really no amused or angry Swedes to write to *Svensk Kem Tidskr* ? Yet woe betide the man who makes a rash remark in his letter to a London editor By return of air-mail post comes an admonitory letter from Minneapolis or Madagascar " It appears to have escaped the notice of Dr X, in his otherwise admirable paper, that I first pointed out the use of seaweed in psoriasis as long ago as —— " But one must admit that there is a certain gratification in knowing that someone in Porto Rico or Pennsylvania is sufficiently interested to question the validity of one's statements

But perhaps the most pleasing feature of the London correspondence columns is the hospitality offered to the most unexpected of esoteric subjects Where else to quote a recent example could one expect to read a discussion on the utility of the word *fax* ? We may rest assured that so long as the catholic nature of the correspondence columns is thus maintained so long will London W C, remain the commodious seat of learning that it is today

* * *

When we were at Blackpool last week doctor Pam ad another attack of er hassma so we called m sister s doctor in an' 'e said we ll 'av er right in a jiffy an' e gave er some little white tablets an next mornin she adn t a sign of it ad yer Pam ?

Nay I were right champion next day

Champion she was so I says to m sister (she s the one as 'ad everything taken out except a hovary) I says m doctor at ome would like to know the name of them tablets nothin' 'as suited our Pam so well so she says go to is surgery an' ask im so I goes along an' e were right nice an said they were called Katie s Own

Perhaps some peripatetic reader could give me a clue ?

* * *

Our hospital is near London and the medical staff, unlike the patients are mostly urban types This can lead to misunderstandings Our Medical Registrar on asking a patient his occupation received the reply ' I'm an artificial inseminator The Registrar was rather taken aback, but, after a moment, inquired brightly Oh do you work for Mr —— (the gynæcologist) in the fertility clinic ? ' The patient stolidly replied " No, Doctor I work in the cattle market "

Letters to the Editor

MEDICAL STAFFS OF MENTAL HOSPITALS

SIR —We are very interested in this correspondence In 1946 our own hospital, which then had a staff of 3 doctors, providing 2 outpatient sessions per week admitted 158 new inpatients In 1956 our medical staff of 7½ doctors (7 full time and 1 part-time) provided 23 outpatients sessions per week and treated 743 new inpatients

It could scarcely be claimed that mental hospitals were extravagantly staffed in 1946, but a comparison of our figures for that year with those for 1956 will show that, relatively speaking, we were very much less favourably placed to treat our patients in 1956, eight years after the inception of the National Health Service In presenting these bare figures no account is taken of the change in scope and character of psychiatric practice in 1956 as compared with ten years earlier, but this aspect of the problem was well emphasised by Dr Strauss and his colleagues in their letter of May 4.

We believe that our situation is not unusual, indeed we know that there are hospitals where the position must be much worse than in our own We consider the increase of medical staffs of mental hospitals to be a problem requiring urgent attention if British psychiatry is to march with the times

HIRSCHSPRUNG'S DISEASE

SIR,—We have recently had under our care a lady of 67 who suffered from this disease in childhood and was operated on for its cure by Frederick Treves in 1897 In view of the advances which have been made in the understanding of the pathology and in the treatment of this condition, we wish to draw attention to Treves's description of this case, in which he expressed his views on the pathogenesis of the dilatation of the colon

Before his time, and indeed since his time as well the enlarged hypertrophied colon had been considered to be the site of the disease, until Swenson and Bill[1] expressed the view that the primary abnormality lay in the narrow normal-looking segment of bowel beyond the dilated portion Although his remarks have been overlooked it is evident that Treves appreciated this fact and based his treatment upon it In a remarkable anticipation of modern concepts he wrote[2]

> I venture to think that there is strong evidence to support the suggestion that all cases of ' idiopathic dilatation of the colon in young children are due to congenital defects in the terminal part of the bowel, that there is in these cases an actual mechanical obstruction and that the dilatation of the bowel is not idiopathic The marked hypertrophy of the distended gut suggests in the most emphatic way that there is an obstruction to be overcome and such hypertrophy is quite inconsistent with the conception of an idiopathic " dilatation of the bowel I am not aware of a previous instance of the treatment of this condition by a radical operation.

After a preliminary colostomy, Treves resected the colon below the splenic flexure, including the narrow segment and the rectum, and he anastomosed the transverse colon to the anal skin The patient has remained fit for many years living an unusually active life The bowels move twice daily, and there is good voluntary control On examination the anus is seen to be replaced by a patulous opening measuring 1 cm laterally by 3 cm anteroposteriorly, through which normal mucosal folds are visible Sphincter action is effected by voluntary contraction of the levatores ani

In 1954 we operated for the relief of obstructive symptoms associated with X-ray appearances suggesting a neoplasm in the ascending colon At laparotomy the colon was found to be mobile and not greatly shortened There was some dilatation but no thickening of the bowel wall A sharp kink in the ascending colon had been caused by adhesions, their division relieved the patient's colic

London, W C 1

H DAINTREE JOHNSON
HAROLD DAVIS
J H EVANS

SIR,—Mr Cooling, in his letter of May 18, advocates State's[1] procedure, in preference to Swenson's, on two grounds—that the results of Swenson's operation are not as good as one would hope, and that it may cause impotence I think this is dangerous advice, for in State's operation part of the aganglionic rectum is left in situ It is all very well to say that the only theoretical criticism of it is that recurrence may follow, but Hirschsprung's disease may kill the patient, and one hardly needs any further objection Before 1948 the majority of sufferers died in infancy or childhood

The dissection of the rectum in Swenson's operation cannot be compared with the wide excision made in adults to remove cancer The essential principle in the rectal dissection in Swenson's operation is that it is made *on* the rectal wall The almost complete absence of bladder complications in the series from Great Ormond Street suggests that a proper dissection does not damage the pelvic nerves Swenson[2] reported that in the 4 adults on whom he had operated ejaculation had not been disturbed He also pointed out that, in 43% of his patients, the lesion extended only to, or just above, the pelvic peritoneal floor, and that such patients would not be helped by a resection above the pelvic floor, for little, if any, aganglionic bowel would be removed Many cases of severe Hirschsprung's disease have resulted from abnormal segments no longer than those which State left in situ One is less concerned about the children, not fully cured, who will grow up to manhood, as about the many who will not grow up

I felt that the results in the series I reported were quite encouraging There are many problems still, but our understanding of them is increasing By due attention to bowel training after operation, close surveillance for the first three years, and the prevention of complications, we can expect improved functional results The great majority of the cases I reported are achieving perfect function, and the results appear as they do because quite a number are taking an understandable time to achieve it

OVERDOSAGE OF VITAMIN D

SIR,—I was most interested in the case of renal colic and persistent hypercalcuria, without hypercalcæmia, following self-administration of vitamin D, reported by *Dr Freedman (March 30)*

In an experimental investigation,[3] in rats and rabbits, polyuria and hypercalcuria were the first signs of vitamin-D intoxication

The animals were given a daily dose of 20 000 I U calciferol per kg body-weight The increase in the urinary excretion of calcium was significant in the rats and highly significant in the rabbits As hypercalcuria developed while the blood calcium level was still normal (in the rats the serum-calcium level remained normal throughout the whole experiment, in the rabbits it increased slightly in the later phase), it must be considered a result of decreased tubular reabsorption of calcium The polyuria likewise points to a tubular disturbance, the increase of the urinary flow was significant in the rats and not significant in the rabbits In view of the very slight histological changes in the tubular cells of the rats at the end of the experiment, it seems possible that these disturbances, caused by calciferol, may arise before morphological changes in the tubular cells

INFLUENZA

SIR,—Those who remember the 1918 influenza pandemic will recall its passage round the world westwards and perhaps see, with me, a possible, even probable, portent in current events in Malaya where influenza is raging

If the events of 1918 should be repeated we might expect a much more rapid westward spread and now is a moment to consider any action European medical authority might be able to take Today both air and surface human-movement control is relevant though I suspect effective isolation is impossible

London, S E 5

GRAHAM E MURPHY

FATAL CARDIAC ARREST WITH FLUOTHANE

SIR,—Unfavourable responses to a new anæsthetic should be reported at once, whether or not they can be satisfactorily explained I therefore report with regret a case of cardiac arrest during the administration of 'Fluothane,' although the data are insufficient to allow definite conclusions to be formed as to its cause

A man of 48 was undergoing partial gastrectomy for chronic duodenal ulceration, in other respects he was healthy As pre anæsthetic medication he was given papaveretum 10 mg and scopolamine 0 4 mg Anæsthesia was induced with thiopentone 500 mg, and was continued with fluothane vaporised from the ether container of a Boyle type II circle absorber and given with oxygen through a cuffed endotracheal tube For relaxation gallamine was given in two doses, each of 20 mg, separated by an interval of a few minutes Soon after giving the second dose, the vaporiser was turned to the sixth notch to obtain deeper anæsthesia, and respiration was assisted This was followed within a minute by a fall in blood pressure to an unrecordable level, and the pulse could not be felt Nevertheless, his appearance did not become alarming he remained a good colour and respiration was not arrested I turned off the vaporiser and washed out his lungs with oxygen, after which his blood pressure returned to its previous level Thenceforward fluothane was administered in small amounts with oxygen

Throughout the operation the blood pressure remained within normal limits and the patient's breathing was satisfactory, its volume and rate were normal and there was no tracheal tug At the end of the operation relaxation was insufficient to allow the abdomen to be closed To meet the difficulty I again turned the vaporiser to the sixth notch and assisted respiration Within one or at most two minutes the blood pressure fell At first, as before, the patient's appearance was not alarming, but after a few moments he became cyanosed and the pupils dilated This condition did not respond to washing out the lungs with oxygen The heart was exposed through an incision in the thorax and was seen to be at a standstill the ventricles were not fibrillating Cardiac massage restored the heart beat, but the period of circulatory arrest had unfortunately been too long to permit survival, the patient died ten days later without having regained consciousness

Reviewing the case, I felt that the most likely explanation of the accident was that, as a result of vaporising fluothane in a closed circuit, a high and lethal concentration had been reached unexpectedly soon If that was so, anæsthetists should be warned against using the anæsthetic in this way It was difficult, however, to rule out the possibility that fluothane like chloroform but unlike ether or cyclopropane, might be capable of arresting the heart at concentrations not much greater than those needed for satisfactory anæsthesia That it has adverse effects on the circulation is suggested by the fall in blood pressure, sometimes to very low levels, that has been repeatedly observed during administrations of the drug even when its concentration was being carefully regulated A case of non-fatal syncope has been reported by Johnstone[1], and I have heard it said that elsewhere a death has occurred, though it has not as yet been reported It should be remembered that Snow, who always insisted on the need for accurate control and limitation of the vapour strength of chloroform, reported in 1858, the year of his death, that he had given that drug to more than 4000 patients with but a single death, and that, he thought, was not attributable to the anæsthetic Those sponsoring fluothane, it seems, have the onus of proving that it is, in fact, safer than chloroform

TRIAL OF 5-HYDROXYTRYPTOPHAN IN PHENYLKETONURIA

Sir,—The cause of the mental defect in phenylketonuria, hitherto unexplained, may be related to a 5-hydroxytryptamine (5 H T) deficiency[2] We are accordingly treating affected patients with 5 hydroxytryptophan, which readily passes the blood-brain barrier, to be decarboxylated to 5-H T[3]

The number of available patients of a suitable age-group is small, and we therefore appeal to doctors who may have phenylketonuric patients (aged 3 years or under) in their care for their help

If the relatives are agreeable to such a patient entering hospital for a period of up to six months for a controlled trial, we should be grateful if the doctor would communicate with Dr C M. B Pare, Maudsley Hospital, Denmark Hill, London, S E 5, for further details

NEONATAL DEATH AND ELECTIVE CÆSAREAN SECTION

Sir —Regarding the article by Dr Strang and his colleagues (May 11) I have no observations to make, other than to express my appreciative interest in it I would, however, like to comment on one point raised by Dr Brown (May 18) He implies that delayed ligation of the umbilical cord might allow continuance of fœtal oxygenation, thus helping to span the gap between delivery and the onset of neonatal respiration I believe that this is not so I have attempted to show[4] that once delivery of the child is completed, placental transmission ceases This is certainly true of such a rapidly transmitted substance as sodium bromide, and I imagine that it applies equally to oxygen I have long held that attempting to deliver oxygen to the fœtus via the mother cannot be proposed as a reason for allowing the child to be anchored to the operation field by its cord Unless it can be agreed (and about this there is still much debate) that a significant quantity of blood can be drained into the child by holding it below the level of the placenta—and furthermore that this is of value—then I can think of no argument against cutting the cord immediately, performing a rapid oral suction and straightaway transferring the child, in a head-down position, to the resuscitation table

HUMANE TECHNIQUE IN THE LABORATORY

Sir,—It gave me great pleasure to read in your issue of May 18 a report of the Ufaw symposium

There must be many medical men lovers of animals who have had an uneasy feeling that the number of animals used for research far exceeded those really necessary, yet most of us would dissociate ourselves from the biased propaganda of the Anti-vivisection Society It is good, therefore, to read the well-balanced views expressed by various speakers at the symposium

Reigate
T W. Preston

CHRONIC BRONCHITIS AND SMOKING

Sir,—I was very glad to read Dr Kay's letter of May 25 However, I want to mention another aspect of the difficulty—smoking in non-smoking compartments

Although the report of Sir John Charles adumbrates the possibility of total prohibition of smoking in public transport, the present position is unsatisfactory Many persons smoke in non smoking compartments and the paper labels are continually being defaced or removed Few junior railway officials show any attitude other than amusement The passenger has often to perform the duty laid upon the railway—the duty to maintain the non smoking compartment Many of the offenders are abusive and prosecutions are few I had trouble 5 days out of 6 in one week in January I have a "dossier" of many official letters but I still have trouble though, I think, less frequently

Are there any suggestions for further action? The constant coughing of smokers must surely be deemed a menace, apart altogether from carcinogens

Department of Pathology
Royal Hospital
Sheffield
J L Edwards

ÆTIOLOGY OF PRE-ECLAMPSIA

Sir,—In my letter (May 4), I defined tensile force, stress, and strain, in relation to uterine action I said that these factors did not exhibit abnormal values in patients with toxæmia of pregnancy and that they tended to have *lower* values than normal in cases of hydramnios and gross uterine distension These statements were based upon measurements made in a number of patients

These facts are now contradicted by Mr Sophian (May 18), and it would be useful to learn the basis of his figures It is noticeable that, with hydramnios, clinical impressions are often at variance with the measurements of pressure and strain

It must be realised that the pressures and strains found by measurement in patients with toxæmia are not different from the values found in normal patients

Sensory nerve-endings, except those reserved for chemical and thermal stimuli, respond to strain only Measuring devices also respond only to strain—i e, changes of length They may be specifically adapted to register changes of strain or to respond to excess strain Force, tensile stress, and pressure are words used to condense observations of strain into convenient language, "coat-hooks" for ideas based on observations of more than one strain

The term "myometrial resistance to stretch," which is used in the correspondence, is another way of saying linear elastic modulus or Young's modulus It is the ratio of stress to strain, and can only be determined by a number of separate strain measurements It is highly improbable that the body would organise a reflex based on the maximum or minimum values of such a complex concept as Young's modulus, even assuming that nerve-endings were available to measure pressure (bulk strain), curvature (differential strain), and linear strain simultaneously.

WARNING OF IDIOSYNCRASY

SIR,—In hospital practice patients are often encountered who have an idiosyncrasy to a drug in common use, such as iodine, penicillin, or chloramphenicol Not infrequently the fact of the existence of a specific idiosyncrasy has been noted in the clinical records of previous hospital examinations, but that fact is often so tucked away in a mass of notes that it may well escape notice by a doctor subsequently examining these notes I have found that a simple and reliable way of bringing idiosyncrasy to the notice of anyone examining a patient's clinical records is for a rubber stamp to be used in wards and outpatient departments It should consist of a lined rectangle 2 by $2\frac{1}{2}$ in, with the word IDIOSYNCRASY at the top of the space

Whenever a hospital doctor discovers that a patient has an idiosyncrasy to any drug he should immediately arrange for that word to be stamped prominently on the front of the folder or on the cover of the clinical notes, and under the word IDIOSYNCRASY should be written the name of the drug or drugs It would be an advantage *if this entry were initialed* by the person making the record

This procedure should save many a patient from the unpleasantness or danger of a widespread dermatitis, or copious vomiting, or other consequence of the administration of a drug to which he is sensitive

Bristol, 9 D G C TASKER

CHRONIC CARBON-MONOXIDE POISONING AS A CARAVANNING RISK

SIR,—Coma due to breathing carbon monoxide in high concentration is, in general, readily diagnosed, and its residua are well recognised, but the possibility of chronic poisoning is less widely appreciated This may affect any one exposed to moderate concentrations over long periods (e g, garage workers and policemen on traffic duty in the "canyons" of New York City), and the following case shows the need to consider it, as a possible cause of obscure symptoms, when patients are living in caravans

A woman of 27 was referred by her family doctor with a month's history of general malaise, nausea, headaches, and dizziness twice she had had rotational vertigo severe enough to make her fall The intensity of symptoms had varied considerably, but they tended to grow worse and latterly she had had transient double vision

Seven years previously, when training as a nurse, she had had an episode of acute depression Three years later she had married a man with disseminated sclerosis, and she was now living with him in a modern luxury caravan on a farm She admitted to anxiety as to the possibility of her contracting disseminated sclerosis

Examination showed slight weakness of the right internal rectus muscle, and when she was admitted to hospital a week later because of more persistent diplopia and the onset of vomiting the right pupil was appreciably larger than the left Otherwise no abnormal signs were found, and investigations (including examination of cerebrospinal fluid and radiography of chest, skull, and nasal sinuses) showed nothing except a mild hypochromic anæmia After four days she was discharged symptom free At a follow up a month later her husband said that her improvement had lasted only a few days He had then sent her to her mother's home for a week and she had again been much better, but all her symptoms had recurred soon after her return to the caravan He had noted that these were more severe when she had cooked a meal at the gas stove

Inquiry showed that the cooking, heating and lighting in the caravan were by 'Calor gas' (butane), and that a few days before the patient's symptoms first appeared additional incandescent mantles had been installed to improve the illumination A sample of blood withdrawn at the clinic was later reported to show 25% saturation with carbon monoxide With more careful attention to ventilation and the use of fewer gas mantles the patient has regained her normal health

The purist may object to the term "chronic carbon monoxide poisoning" on the grounds that carbon monoxide is not a cumulative poison, but here the term seems fully justified A working principle for those whose occupations involve exposure to carbon monoxide is that they should spend at least two thirds of each day in an uncontaminated atmosphere in the case described above, the husband, who was away from the caravan during the day, remained well

The symptoms are in no way specific and the diagnosis is unlikely to be considered unless there is reason to suspect exposure to the gas Such suspicion should be aroused by the fact that a patient is using a caravan for permanent residence In these essentially primitive though often luxurious, holiday dwellings adequate ventilation without draughts is not easily obtained The installation of butane or solid-fuel heating and cooking appliances can hardly have been envisaged by the original designers

Lancaster G M BARRETT

MASSIVE THROMBOPHLEBITIS

SIR,—It was only recently that I read the interesting paper by Mr Catchpole (Feb 16) Four years ago I saw a similar case in which a patient died after nephrectomy for pyonephrosis The fact that exceptionally thrombotic occlusion of the *femoral* vein leads to a "blue leg" seems to be due to the usually concomitant arterial spasm which prevents the rapid immobilisation of a large quantity of blood in the lower limb When it is intense, this contraction can even produce a clinical picture closely resembling arterial embolism Only if this reflex reaction is entirely missing can the syndrome of "phlegmasia cærulea" result

Jugenheim Germany EDUARD MELCHIOR

"TO COMFORT ALWAYS"

SIR,—Last night I listened to one of the items in the wireless programme "To Comfort Always," nine tenths "blurb" wrapped *round one tenth* of misunderstood fact I do not suppose these well meaning people realise the enormous amount of harm they are doing, but aided by some others who call themselves psychiatrists they are increasing the number of mental patients In an address which you printed on May 18 the chairman of the Board of Control said that, whereas the number of psychotic stayed about the same in this country (about 130,000), the number of voluntary patients was going up "by leaps and bounds" This series should make it bound further

Why? Chiefly because mankind has been *looking* inwards, led into doing so by the psychiatrists and their silly dogmas But man's mental processes were formed in the million years of his entity *for the practical ends* of survival and propagation Looking inwards was harmful to him That is why men and women forget their childhood, as the psychiatrists themselves have frequently observed A classical example of this comes *from* Galton who found *a number* of intellectual men who scoffed at the idea that anyone could think in pictures, think visually, *though*, of course, they themselves had done so right up to early manhood at any rate To psycho analyse anyone is just as dangerous to him as to do a laparotomy on him—more so probably because it is a dissection of a more delicate organ—and *is only* very occasionally justified Sometimes the analyst leaves a dirty swab in the mind by suggestive questioning, as Freud did by *suggesting* to his female hysterics that they had been sexually interfered with by their fathers in early childhood [1] Later he realised this, but nearly all his followers have neglected the clue that stares them in the face—that the introspective are the least stable members of the community

---

[1] Sargant W Battle for the Mind London 1957 p 159

But the culminating stupidity of this series was in the title of the last talk, "The Price of Progress", the idea being that the stresses of modern life are the cause of mental breakdowns But the valid stresses of life which dominated men's minds from earliest times have gone, and gone recently I remember the time when the threat of losing his job made a man blanch, for it meant that his family and he would starve, when a penniless existence in the workhouse was dreaded by most ageing people, when the fear of being physically hurt guided the young and religions kept their grip by threatening torture after death, eternal torture, stresses and fears which were also stays I am not saying that they are desirable, but that modern stresses are much less severe If the social animal man has not got reasons for fear, he will invent them by making up conventions and codes A man without fear degenerates, as is seen in those with power

"To Comfort Always" is the motto of the mother who spoils her child, spoils him for the rough and tumble that is life, to threaten, to punish, to stimulate, to deride, to inspire, to ignore, also have their place Mine is a lone voice in the wilderness, crying out not for the first time that much of our modern psychiatry is damned bad natural history and worse common sense

Beckley, Rye C G LEAROYD

TOWARDS SAFER CLOTHING

SIR,—Your leading article last week prompts me to record a disquieting personal experience

Some short time ago my younger son was in need of some new pyjamas I suggested to my wife that they should be made of flame proofed material and she attempted to buy them locally Few of the shops approached had ever heard of flame proofed material and none stocked it I consequently wrote to the advisory service of a national magazine devoted to household affairs A reply bearing the names of three large stores in the London area was speedily received Consecutive postal inquiries revealed that one store stocked flame proofed material and another had nightgowns, none had pyjamas made of this material Perhaps one of your readers can tell me where I can buy them ?

Cambridge. H J WOODLIFF

FIBROSITIC PAIN

SIR,—Dr Louis Moss (May 25) emphasises the concept that "trigger spots" can cause myalgic and fibrositic pain Although this may be conceded, it must not be overlooked that 90% of these pains are of psychological origin In states of mental conflict there is an increase of electrical potential which must "explode" some where Any part of the body can be involved and any slight injury creates a "fixation" This explains the multiplicity of remedies and their futility in so called "rheumatic" pains

London W 1 M W BROWDY

SALMONELLÆ IN REPTILES

SIR,—Dr Ruskin (May 11) suggests the abundance of lizards in the hot climate of Ibadan keeps down the fly population I hardly think this is the answer but rather the result of the hot sun killing the fly larvæ

In the past I have kept dozens of Agama lizards (*A planiceps*) in captivity, and flies whether alive or dead were never a favourite article of diet with them

Some years ago when I was working in Ghana (Accra) flies were a menace, yet lizards were far more prolific than in Ibadan, but of course the climate of Accra is very humid

University College Hospital
Ibadan Nigeria STANLEY F WOODWARD

METALLIC CORROSION IN ORTHOPÆDIC SURGERY

SIR,—In considering the effects of metals in orthopædic surgery, it is useful, in a practical world, to differentiate between corrosion that is surgically serious and corrosion that, by present standards, is not When "micro" methods are used to detect it, corrosion can be discovered (both in the metal and in the tissues) with almost all metals, including the "safe" metals S Mo and 'Vitallium,' and any surgeon who insists on complete freedom from all trace of corrosion has at present no recourse but to forgo the use of metal altogether

Where Dr Bowden and his colleagues, in their article last week[1] say that the use of mixed metals *is* by far the most important cause of corrosion I would be more explicit and say that, apart from extraordinary metals such as aluminium magnesium, &c,[2] all the serious corrosion ever seen can be accounted for by one group of steels, which corrode severely even without the stimulus of a dissimilar metal, and by one particular pair of stainless steels in combination The group of steels are ordinary steel (1936), vanadium steel (1936), and chrome steel (? 1946), and the stainless combination is the E M S (1954) × F S L combination (The dates given are when the steels finally ceased being sold) Capener's implied criticism[3] of F S L cannot be justified on the grounds of corrosion because, so far as my experience and my search of the literature goes, *no* authenticated case of serious corrosion in unmixed F S L has ever been described

The later paragraphs of the article by Dr Bowden and his colleagues are misleading, I believe, in so far as they imply that corrosion caused purely by metallic transfer (from screwdrivers, drills, &c) can give rise to serious trouble Although they established[4] that corrosion does occur from this cause, they never demonstrated it above the "micro" level and in correspondence with Wright and Axon[5] they acknowledged this fact Subsequently, however, they attempted to explain[6] the more serious clinical cases of corrosion quoted by Wright and Axon and the nine cases collected by Laing himself[7] on the metallic-transfer theory

Of this, I contend, they have not established a satisfactory proof The weakness of their argument lies in the link between the in-vitro and the clinical findings Laing thought that the metal in his clinical cases was S Mo, in which case his conclusion that the corrosion seen must be due entirely to metallic transfer would be justified But there is evidence to suggest that he fell into the trap of accepting the metal identification on trust The firm from whom the metal was probably purchased did not, in fact, start selling S Mo screws and bolts until after most of Laing's cases had been operated upon It is possible therefore that in these cases the corrosion was due to the E M S × F S L combination as it had been in Wright and Axon's cases

In order to establish a proper sense of proportion, I would elaborate a statement I made previously—namely, that at the Birmingham Accident Hospital we have made sure that we never use chrome steel (or any of the more antiquated steels) or the E M S × F S L combination and have not had any case of serious corrosion amongst the 2000 cases of internal fixation since this was done We have not changed over from

IMMUNOLOGY OF THYROID DISEASE

SIR,—It is to be regretted that your admirable leader last week on the new concept of thyroid disease makes no mention of the pioneer work of Loeb on tissue transplantation and organ specificity, a comprehensive account of which is given in his book *The Biological Basis of Individuality*

Loeb probably did more experimental work on this subject than any other investigator before or since—work involving transplantation of every variety of tissue and organ under almost any conceivable given set of circumstances Those of us interested in tissue transplantation are becoming more and more aware that Loeb has already anticipated most of the "original" work and new "theories" of today, many of which are, in fact, his ideas wrapped up in a more modern terminology Just as today the neurohistologist finds himself confirming Cajal's work of fifty years ago, much of modern grafting experiment is a repetition of the work of Loeb Had his book been published today, instead of 1945, it would in many ways have been regarded as the most up to date and authoritative work on the subject

CANCER AND ATHEROSCLEROSIS

SIR,—I was much interested by your annotation of Feb 16 I think it would be useful to mention the original work of S G Zondek on malignant growths and essential hypertension[1] and on the inhibiting influence of essential hypertension on malignant growths and rheumatoid arthritis[2]

Hadassah Municipal Hospital,
Tel Aviv Israel I LURJE

IDENTIFICATION OF THE "FOURTH TYPE" OF POLIOMYELITIS VIRUS

SIR,—In January, 1956, the Russian virologists Chumakov et al[3] reported that they had isolated a new immunological type of poliomyelitis virus from the fæces of three children with bulbospinal poliomyelitis This they designated type IV poliomyelitis virus

The three strains were named AB IV, MK IV, and GZ IV The first two were isolated in monkeys (*Rhesus macacus*) in which they gave rise to paralyses and pathological anatomical changes which resembled those of poliomyelitis Brain and spinal-cord passage material from monkeys caused paralyses when injected into suckling mice, suckling hamsters, and suckling cotton rats as well as in adult cotton-rats Relatively high virus titres were found in most of the viscera of the suckling cotton rats On histopathological examination of the central nervous system, poliomyelitis like changes were found in the monkeys as well as in the cotton rats The strain GZ IV was isolated in adult cotton rats and in newborn mice, and had the same animal pathogenicity as the other two None of the strains were pathogenic for adult mice

The pathogenicity of the virus for monkeys and cotton rats was regarded by Chumakov et al as indicating that the virus belonged to the poliovirus group By extensive cross immunisation experiments on monkeys and cotton rats they were able to show that the strains were identical immunologically but that they were not identical with the poliomyelitis types I, II, and III

One of the strains, AB IV (brain material from cotton rat), was kindly sent by Dr Chumakov to the Department of Virus Research here for further study

The passage material was *inoculated into tissue cultures* of human embryonic lung No degenerative changes could be detected In spite of the pathogenicity of the virus for monkeys, it was suspected to belong *to the Coxsackie* group In suckling mice the typical flaccid paralyses were found After a few passages the material reached a titre of about 10^{-6}, and, by neutralisation tests with hyper immune sera against Dalldorf type strains A_1–A_{19} and B_1–B_6 it was found that the strains under investigation were immunologically identical with Coxsackie virus type A7

CROSSWISE NEUTRALISATION TESTS IN SUCKLING MICE WITH THE RUSSIAN STRAIN AB IV AND COXSACKIE VIRUS TYPE A7

—	Guineapig antiserum type A7	Rabbit antiserum strain AB IV (Russian)	Mouse antiserum strain AB IV (Swedish)
Virus strain AB IV	≧3·5*	2·2	≧3·5
Coxsackie virus type A7	≧3·5	1·6	≧3·5

* Serum titre expressed in neg log

This was confirmed by crosswise neutralisation tests (see accompanying table)

Histopathological examination of one of the mice with typical flaccid paralyses showed diffuse and very pronounced changes in the skeletal muscles The lesions were mainly necrotic and necrobiotic in nature No lesions were observed in the brain, cord, or other organs The histological picture of the muscles resembled in principle that associated with Coxsackie virus (subgroup A) infections in mice

The original Russian material was inoculated intracerebrally into cotton rats aged 8–9 weeks and 1 year Both groups of animals came down with flaccid paralyses after an incubation period of 5–7 days

Microscopic examination of a large number of muscle groups as well as viscera of cotton rats gave *negative results*, and no lesions could be found in the brain In the cord, however, limited and slight changes were seen in *all four* animals examined These changes were *localised to the grey* matter, in particular to the anterior horns, but in a few instances lesions were also found in the posterior horns In the *affected areas, necrotic and necrobiotic* ganglion cells were observed with destruction of the tigroid substance Apart from these changes, there were small accumulations *of inflammatory* cells, principally *polymorphonuclear* leucocytes

It therefore appears, from the Russian results and our own, that a virus strain immunologically *identical* with Coxsackie virus type A7 can produce a poliomyelitis like syndrome in monkeys A new observation is also the pathogenicity for adult cotton-rats

Habel,[4] who studied the Russian type IV poliomyelitis virus thoroughly, *could confirm that the agent* was immunologically identical with Coxsackie virus type A7 He performed a series of blind passages in tissue culture and found a weak *cytopathogenicity appearing* after 11 passages After 30 passages the changes were pronounced In this connection it may be mentioned that Svedmyr et al,[5] in cooperation with *Johnsson,*[6] *have* studied two Coxsackie type A7 strains which were isolated from fæcal specimens in tissue *culture* One of them was also isolated directly in suckling mice The cytopathogenicity to tissue cultures was *still* weak and irregular after fifteen passages

Horstmann and Manuelidis[7] observed ataxia, tremor, and weakness after inoculation of one of the Russian strains in monkeys They found lesions similar to those of poliomyelitis but somewhat *differently localised*

The question of the connection between the Russian strains and the clinical manifestations in the three children must be left open at the moment Attention can be directed to pathological electro-encephalograms observed by Johnsson[8] in three cases of meningo-encephalitis, in which Coxsackie virus type A7 was isolated During 1954 type A7 was isolated from about twenty cases of meningo-encephalitis or aseptic meningitis[9]

AUSCULTATION OF THE SKULL IN PAGET'S DISEASE

SIR,—The auscultatory physical sign of Paget's disease of the skull is said to be a bruit arising as a consequence of hæmodynamic changes

A far more frequent finding, however, seems to be an abnormal conduction of breath-sounds through the altered bone What is heard in fact sounds like bronchial breathing, this is absent over normal skulls

Provided this observation is valid, it seems very likely that it has been recorded before I have noted this abnormal breath sound conduction in about twenty patients with Paget's disease of the skull, and would be glad to learn of any reference to it or other experience of it

St Stephen's Hospital,
London S W 10

D HYWEL DAVIES

DIARRHŒA AFTER PENICILLIN INJECTION

SIR,—Diarrhœa is a feature of many allergies but is not often cited as a reaction to penicillin

A young woman was given penicillin (for the first time, she thought), for " fever " 3–4 hours later her temperature rose, the injection site became hard and red, and she had diarrhœa lasting 2 days 2 years later, when aged 27, she had " sinusitis " and was given procaine penicillin 300,000 units intramuscularly 5–6 hours later she vomited and had several watery stools in the course of a few hours Another injection, two days later, was followed by redness and induration at both injection sites, but no further diarrhœa No more penicillin was given 8 days later generalised urticaria appeared This settled after antihistamine treatment

It seems possible that diarrhœa may be an allergic reaction to penicillin

Giva time Israel

KENNETH KATTAN

TELEVISION AND MEDICINE

SIR,—In last week's annotation you say that the first colour television demonstrations of surgery in Great Britain will take place this summer As a matter of accuracy it should be placed again on record[10] that colour television of surgery was shown at the International Congress of Ophthalmology in 1950 at St Thomas's Hospital On that occasion British equipment, by Pye of Cambridge, was used throughout, a camera in the theatre transmitted the image to six receivers (one in the control room, one in the theatre, and four in the display room) It was in use almost every day for four weeks

You also say that " a medical student gains little from watching operations on a screen (as) is now appreciated by most British film makers " While few would quarrel with this statement if applied to undergraduate medical students, to whom you are obviously referring, it should not be allowed to go by default that surgical films are a most valuable means of teaching postgraduate surgery if one considers not one's own medical school, but the world as a whole as one's lecture theatre And surely it is the very merit of mass media visual techniques, whether television or film, that they can extend the ability for detailed observations beyond the restricted confines of the operating-theatre

London, W 1

Parliament

QUESTION TIME

Shortage of Radiographers

In answer to questions on this subject from nine members **Mr DENNIS VOSPER**, the Minister of Health, replied The number of radiographers in the hospital service in England and Wales at the end of 1952 was 2652 whole time and 199 part time The provisional figures at the end of 1956 were 3087 and 289, respectively There has been, therefore, a marked increase, but there is evidence to suggest that it has not been enough to meet the increased demand for X ray services A sample inquiry in four hospital regions a year ago indicated that there was a shortage of 16% on establishment, and that not more than half the annual loss was due to reasons other than retirement, marriage, or domestic reasons

Since then, in November last, the salaries were substantially increased and the staffing structure improved following an award of the Industrial Court The salary of the basic grade is now £420–485 per annum, and of the highest grade of superintendent radiographer £675–850 In my view, it is too early to assess the effect of these increases Meanwhile, I have asked hospital boards for information about the staffing of radiography departments and the intake of students in order to obtain a full up to date picture of the position The last return has just been received

Dr BARNETT STROSS Is the Minister aware that the number of X ray examinations taking place today are roughly twice as many as compared with those that took place before the National Health Service was instituted ? Does he not agree that the present grades of remuneration that he has quoted—for example, the £420 minimum scale—should be £650 if it were evaluated with the minimum grade before the war and brought up to that standard in accordance with the cost of living ? Will he promise to look seriously into this matter and ensure that the long waiting lists, evidence of which is to be found in the hospitals, and the fact that people have to wait weeks before they can be X rayed, are brought to an end ?—**Mr VOSPER** The situation is unsatisfactory, but the existence of a gap between demand and supply is not confined to radiography On the other hand, there has been an increase of no less than 50% since 1949 As for remuneration, this is not fixed by me but by the Whitley machinery, and in this case was settled by the Industrial Court only six months ago

Mr J C JENNINGS May I ask whether the Minister is not aware that there is a serious wastage of trained personnel in this service, and does he not agree that it is a very serious matter when trained personnel leave this service to take up positions with higher remuneration ?—**Mr VOSPER** It is true that there is a wastage, and I hope that one of the results of my inquiry may be to determine more closely the reasons for it

Mr ARTHUR BLENKINSOP Will the Minister keep in mind also the very considerable wastage of all kinds of other professional workers in hospitals, as well as radiographers ?—**Mr VOSPER** It is true that both the deficiency and the wastage apply to all medical auxiliaries and to many classes of people employed in the hospital service

Lieut Colonel W H BROMLEY DAVENPORT In view of the increased importance of radiography and the obvious anxiety of those employed in this service, will the Minister give every possible consideration to this matter ?—**Mr VOSPER** One other factor which the House must bear in mind is that this matter may be affected by the committee under the chairmanship of Lord Adrian which is investigating radiological hazards Therefore, the demand in future may not be as great as it is today

The Affair at Bath

Mr I J PITMAN asked the Minister if he was aware that the premises of the Royal National Hospital for Rheumatic

---

[8] Johnsson T J A Virological and Clinical Study of Infections with Coxsackie Virus Uddevalla 1955

[9] Berglund A Johnsson T J Data to be published

[10] See *Lancet* 1950 ii 190

Diseases at Bath were in a state of decrepitude and danger by risk of fire, and, in view of the national service and importance of this hospital as a centre for the treatment of rheumatic diseases, what steps he intended to take to expedite the necessary work of reconstruction —Mr VOSPER replied I am aware that this hospital falls short of modern standards, and I am at present examining the proposal of the South-Western Regional Hospital Board that the project to restore it should be included in the programme of major building projects which are financed centrally Mr PITMAN May I ask the Minister to urge the national need in serving the whole country upon the regional hospital board whose responsibility is primarily regional —Mr VOSPER I have that in mind Of course, this is not by any means the only hospital which draws its patients from all over the country

Mr THOMAS WILLIAMS Is the Minister aware that this particular hospital received donations of nearly £90,000 to rebuild the hospital before the war ?—Mr VOSPER I do not think that that point is particularly material, the money has to come out of the same pocket, whichever way the financing is done The difficulty is that priorities have changed since this hospital was first put down for rebuilding and more urgent needs have arisen

Domiciliary Psychiatry

Dr DONALD JOHNSON asked the Minister of Health if he was aware that, as a consequence of the South West Metropolitan Regional Hospital Board experiment in domiciliary psychiatry in the Worthing area, the admissions to mental hospital in that area had decreased from 166 in the first quarter of 1956 to 64 in the first quarter of 1957, and, in view of the urgent need to relieve the present overcrowding in mental hospitals throughout the country, how soon he would be extending a similar service to the remainder of the country —Mr VOSPER replied I am aware of this experimental scheme, which resembles other schemes in operation elsewhere in this country in reducing the number of admissions to mental hospitals Its early results are promising, and I will watch its progress with interest, but it is too early to come to a final conclusion about it Dr JOHNSON Does not the Minister agree that this is the simplest and most effective way of curing the overcrowding in mental hospitals, and will he, when coming to a conclusion on the subject, expedite matters so as to introduce these experiments on the widest base possible ?—Mr VOSPER I have studied this scheme I think it is most promising but I am sure that its authors would be the first to agree that it needs more time before we can be quite certain as to its results Dr EDITH SUMMERSKILL Can the Minister say whether there are enough psychiatrists in the country to provide a domiciliary psychiatric service ?—Mr VOSPER It would not be possible to establish a scheme like this in every area of the country immediately, but, if successful, and if the Royal Commission recommends an extension, most certainly we will do what we can about it

Consultants, S H M O s, and Senior Registrars

The number of consultants, S H M O s, and senior registrars in the National Health Service in England and Wales in 1949 and in 1956 was as follows

—	December 1949	June 1956
Consultants	5190	6695
Senior hospital medical and dental officers	2000*	2534
Senior registrars	1400*	1107

Glasgow Tuberculosis Campaign

The clinical assessment of patients identified in the Glasgow mass X ray campaign is still proceeding On May 21, 947 persons had been admitted to hospitals for further investigation or treatment Another 100 people were due to go into hospital

Cost of Prescriptions

The average cost per prescription dispensed in England and Wales in February was 5s 7 87d From a sample it is estimated that the average cost for March was about ½d more than in February

Medicine and the Law

The General Practitioner in the Witness-box

BY A METROPOLITAN POLICE SURGEON

I HAVE attended almost all the London courts many times, and have often listened to other doctors giving evidence Some of them leave the witness box looking very unhappy, and the impression they have left on the court has been equally unhappy There seems to me to be one chief reason for this An expert witness giving evidence is supposed to tell the whole truth and nothing but the truth He should not show bias, and these doctors have

The commonest example is the "drunk in charge" case in which the doctor has been called by the defence His mental attitude on entering the witness box seems to be something like this

> I shall tell the truth, but if the wind of unadulterated truth seems to blow rather cold on my lamb of a patient (who is perhaps about to be shorn of his driving licence), I shall temper it the least little trifle

Entering a witness box in that frame of mind is dangerous It is, I believe, the chief cause of the trouble that general practitioners make for themselves in court, when they undertake as amateurs, to engage in a bout of verbal fencing with a professional

There are several ways in which a doctor can try to evade an awkward question *They are all bad*

He can discard all his scruples and tell a lie Here are examples of things I have heard stated on oath by three different doctors

> "He was perfectly sober when I examined him and could not have been under the influence of alcohol an hour and a half before that"
>
> "I examined him for the first time two and a half months after he was arrested At the time of the police surgeon's examination he was suffering from influenza The police surgeon failed to diagnose this"
>
> "He is a nervous man, prone to bilious attacks His stomach is so irritable that it could not retain enough alcohol to put him under the influence He would be sick first"

I have heard it stated in court that practically all the symptoms and signs of mild drunkenness, except the smell of the breath, can be produced by high blood pressure, low blood pressure, exhaustion, sleeplessness due to toothache, carbon-monoxide poisoning, aspirin poisoning, amphetamine poisoning, congenital derangement of the cerebellum, influenza, sinusitis, middle-ear disease, Ménière's disease, cerebral arteriosclerosis, mild surgical shock, and hypoglycæmia (it is true, of course, that an overdose of insulin can simulate drunkenness very closely)

Another way of trying to evade an awkward question is to break off the engagement by retiring behind a smoke screen of abstruse verbiage—a technique which is liable to be poorly received Another way is to give an answer, but not an answer to the question that was asked This is the sort of thing that can happen

> "Doctor, would having taken four aspirin tablets cause this man to be rude to the Inspector ?"
>
> "He must have had some reason for taking four aspirin"
>
> "Doctor! Would having taken four aspirins cause this man to be rude to the Inspector ?"
>
> "We have only the Inspector's word for it that he was rude"
>
> "Doctor!! Would, &c ?"
>
> "You can't just consider the aspirins alone You must include all the other circumstances"
>
> "Doctor!!! Would &c ?"
>
> "No"

"No" is the right answer Everybody in court except the expert witness knew that all the time

A very common pitfall, and perhaps the most ruinous of all, is to start to fumble and mumble, hunting about for an answer that is not too damaging and yet approximately true The result is usually deplorable Counsel knows at once that the witness is trying to hide something He leaps to the kill and keeps on leaping until he gets it

Damaging admissions *freely made* enhance the credibility of the rest of one's evidence enormously

My advice to the general-practitioner witness is this You are going to swear to tell the truth, the whole truth, and nothing but the truth Do not deviate from the terms of that oath You will not then leave the witness box looking, and no doubt feeling, a shattered wreck

Your patient may not be entirely pleased with your performance, but he can have no legitimate grievance Warn him beforehand that you are terrified of the witness-box and will on no account embark on any funny business

Obituary

HAVEN EMERSON

M D Columbia

Dr Emerson, emeritus professor of public health practice at Columbia University, a former health commissioner of New York City, and chief epidemiologist in the American Expeditionary Force in the 1914–18 war, died on May 22 at Greenport, Long Island, at the age of 82 His age and his appointments might suggest a serene retirement, but the spirit which had enlivened and made so effective his fifty years' work in the public-health service was still lively, and only a few months ago he was energetically denouncing those who opposed the fluoridation of civic water-supplies

He came of a family with a tradition of public service His father, Dr John Haven Emerson, was a nephew of the essayist and one of New York's first public-health physicians A few years after qualifying in 1899, Haven Emerson joined his father in this work and for the next fifty years he took an energetic, witty, and imaginative part in every measure to control communicable diseases and raise the hygienic standards of the people He treated the last case of cholera in New York, he helped to fight the 1916 poliomyelitis epidemic, he introduced mass radiography for the city's population, he early advocated and obtained the pasteurisation of the milk-supply He has been described, not without good cause, as a "superb and dedicated nagger in what the public barely knew to be the public interest"

His work in the 1914–18 war and later for the League of Nations widened his range of action His relief work in Germany and Greece led to his studies on diet, and crop deficiencies He was a man who was easily, and usefully, irritated to action, and his dislike of the illogical variations of national medical terminology led him to work for an international system

Not unexpectedly, with his drive and independence went a distaste for over-formality in administration and over-mechanisation in technique He once informed some of his more conventional colleagues that "the test of a doctor s skill is what he can do with his brains, his faith, and carbolic soap"

R H P, one of his many English friends, writes

A year ago I spent the day with Haven Emerson and his wife in their home at Greenport, Long Island He was as alert mentally and physically (apparently) as he had ever been Although as intolerant as ever of the "fuzzy minded nitwits who speak with authority concerning matters they do not understand" he was most tolerant of and gentle to all the trees shrubs and flowers on his fine estate At lunch over which he presided with his usual dignity, there was not an item which had not been produced on his farm

He was proud of his ancestors proud of his country, and proud of the achievements of public health Although ripe in years, his enthusiasm and his confidence in the success of the great fight for good health for all mankind might well be the envy of any health officer at the height of his career

Diary of the Week

JUNE 2 TO 8

Sunday, 2nd

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL, University Street, W C 1

Notes and News

A SIMPLE PRECAUTION

YOUNG doctors in the London area should consider carefully the advantages offered by a little known but most helpful body—the Society for Relief of Widows and Orphans of Medical Men Founded in 1788, this society has a long record of good work, and even in these days of superannuation schemes its aid is sometimes invaluable to a doctor's dependants who find themselves in difficulties because of his death after a long illness or unexpectedly Such aid could be given more widely if more doctors would qualify for it by joining the society

For membership, the candidate must be a male registered medical practitioner who at the time of election is living within 20 miles of Charing Cross The annual subscription is 2 guineas for members under 35 on admission, 3 guineas for those aged 35–45, and 4 guineas for those over 45 A medical examination may be required, and relief is given only to widows and orphans of deceased members of not less than three years' standing The present income limit for eligibility for grants is £150 per annum, but the directors can consider cases in which it does not exceed £200 The society has resources of over £120,000, and last year it distributed £4130

The president is Sir Robert Young Inquiries about membership should go to the secretary, Dr J A Struthers, at 11, Chandos Street, Cavendish Square, London, W 1

WORLD HEALTH ASSEMBLY

AT the tenth World Health Assembly, the committee on programme and budget recommended a budget of just over $13,500 000 for 1958, and this figure was adopted by the assembly (the budget for this year is $12,550,000) The committee asked W H O to undertake a research programme on the epidemiology of cancer carcinogens in the environment would be studied and comparative statistics published W H O would also advise on cancer registration and definitions of nomenclature

The committee called for the training of health physicists and doctors in the public health aspects of atomic energy A course in health physics will be held in Zürich this year, and the disposal of radioactive wastes is being studied The World Federation for Mental Health has drawn attention to the mental and social factors involved in the use of atomic energy A proposal to appeal for a ban on atomic bomb tests was ruled out of order by the chairman, whose rule was upheld by a vote of the committee

The malaria fund stands at $123,800, but more money is needed It is estimated that malaria could be eradicated in some of the larger countries of Asia if $15 million a year were provided for five years The committee emphasised the need for research into mosquito resistance to insecticides, and the dangers of reinfection across frontiers

On the recommendation of the committee on administration, finance, and legal matters, the assembly asked Dr M G Candau to renew his contract as Director General for another five years

PROFESSIONS IN A CHANGING SOCIETY

Prof W MANSFIELD COOPER, vice chancellor of the University of Manchester, spoke on this subject in his address at the annual meeting of the Manchester Medical Society on May 1 Dr J F Wilkinson, the president, was in the chair

It was curious he said, that almost the whole of the literature on the subject was peripheral and took the essence of a profession for granted Perhaps the only way of approach was by a study of characteristics common to all the professions The first characteristic was that a profession must be 'learned" techniques might be essential, but they were the accidents not the essence of professional activity Secondly, the object of professional activity was never primarily material reward as was shown to some extent by a study of the right to sue in respect of fees and expenses in the two professions of medicine and law Perhaps the most serious development at the present time was the growth of pseudo learned vocations seeking professional status and seeking legislative recognition the object which was partly exclusion from or control of entry to the profession and thus the limitation of competition A study of American trends showed how very far this had gone

Professor Cooper then set out to define the circumstances in which a new profession might emerge in modern society To seek State recognition might solve certain problems but it created others, particularly in relation to the essential characteristic of professional autonomy Here the increasing dependence of the medical profession on the National Health Service produced problems of a quite acute character

A study of recent trends suggested that in a democratic society the professions must on the one hand attempt to interpret themselves intelligibly to that society but must on proper occasions resist popular clamour In medicine the situation looked brighter than it had a few years ago, for the courts, after a series of cases in which the patient had been successful, had become much more critical of actions against the medical practitioner and were obviously attempting to understand the difficulties in the path of the doctor

THE ROYAL SOCIETY

DINOSAURS' eggs sat beside a model of the insulin molecule at the society's conversazione on May 23 Demonstrations and exhibits of strictly medical interest seemed quite staid compared with some of the dashing affairs elsewhere For instance, what physician or surgeon could hope to produce results as impressive as those modestly displayed by Dr P W Brian and his colleagues, of the I C I Akers Research Laboratories, who had been studying the stimulation of plant growth by gibberellic acid? This substance, a metabolite of a fungus pathogenic to plants, can stimulate the growth of stem internodes and sometimes leaves in growing plants It has been shown to "reverse" genetic dwarfism in some plants The I C I team say cautiously that far more experience is needed before the practical significance of these effects can be assessed, but that did not prevent them from nearly raising the roof of Burlington House with their monster plants

Dr P A Merton, of the Medical Research Council's neurological research unit at Queen Square, very effectively demonstrated compensatory rolling movements of the eye in man He had persuaded some strong stomached friends to sit in a swing which then rotated about the line of sight Through a magnifying system, it was then possible to examine the eye and to note how it rolled in its socket in the opposite direction to the movement of the head so as to minimise the relative rotation of the image on the retina This accurate stabilising mechanism enables vision to remain clear even during violent exertions

The midwifery department of Glasgow University and the physics department, Western Regional Hospital Board Glasgow, explained the artificial respirator they have been using for newborn infants This is a servo respirator in which a baby's feeble effort to take a breath is detected, amplified and used to release a supply of air or oxygen from a cylinder The infant thus gets air when he wants it and his breathing is not dependent on his own perhaps feeble strength

Inherited differences in certain human serum proteins known as haptoglobulins were demonstrated by Dr A C Allison and Mrs W ap Rees, of Oxford When red cells are lysed in the circulation, the liberated hæmoglobin is normally bound to the haptoglobulins In most subjects hæmoglobin appears in the urine only when its level in the plasma exceeds the combining power of the haptoglobulins, i e, only after severe hæmolysis People without haptoglobulins are much more liable to hæmoglobinuria and therefore to iron deficiency

The striking coloured model of the insulin molecule was brought by Dr F Sanger, F R S, from the department of biochemistry at Cambridge (the dinosaurs' eggs came from the British Museum) Dr K M Smith, F R S and his colleagues at the Agricultural Research Council's virus research unit showed how X ray analysis and electron microscopy had been used to deduce the structure of plant viruses

MEDICINE AND THE HEALTH SERVICE

AT the annual meeting of the United Sheffield Hospitals on April 25, Dr E J WAYNE, regius professor of medicine in the University of Glasgow, spoke on the Changing Face of Medicine

Prevention, he said, is always less dramatic than the results of failure to prevent, just as a Major Road Ahead sign is less exciting than an ambulance and a tangled mass of wreckage Nevertheless the vastly improved health of the community today is probably to be attributed more to the prevention of disease than to the potent remedies which we now possess

Turning to the progress made in the administration of medical services, he pointed out that advances in medical scien are of little value to the community unless they can be made readily available through what has been called "medical engineering" In general practice the danger of the present position is that the patient is tending to regard the practitioner not as an adviser but as a person to give prescriptions and certificates or to refer him to a specialist if the illness is more than very minor While the quality of the hospital service has on the whole notably risen since 1947, Professor Wayne drew attention to the major problem created in most hospitals today by the disabled and often aged patient who cannot return to his own home "There are far too few suitable long stay hospitals for such persons, with the result that they fill the beds of hospitals expensively staffed and equipped for quite different purposes No business concern would tolerate this type of waste, which is equivalent to using a factory equipped for making precision instruments for the manufacture of tintacks Yet to a greater or less degree it is a feature of our hospital service in all parts of Great Britain"

It has been said that while money may not lead to happiness at least it enables one to be miserable in comfort In the same way, Professor Wayne said, the National Health Service enables sickness to be endured under better conditions by early treatment at home or by admission to hospital But, apart from dealing quickly with the acute infections and surgical emergencies it has not in a statistical sense greatly increased the general health of the community "One sometimes wonders," he added, "if we are getting an adequate return for the £50 million we spend annually on drugs Many of these are used to relieve comparatively trivial symptoms and the public might be just as well off without them"

University of Cambridge

On May 18 the following degrees were conferred

M Chir—R B McGrigor
M.B B Chir—G J Jewell
M.B—P D Mulcahy Mary E Jewell.

Pinsent Darwin studentship—Applications are invited for this studentship in mental pathology

Its annual value is £500, and the normal tenure is three years Applicants should write before July 1 to the secretary of the studentship Psychological Laboratory Cambridge stating their age and qualifications and the general nature of the research that they wish to undertake

Royal College of Obstetricians and Gynæcologists

At a meeting of the council held on May 25, with Sir Charles Read, the president, in the chair, the following were elected to the council

As representatives of the fellows W C W Nixon F E Stabler, T N MacGregor C H G Macafee
As representatives of the members T L T Lewis Robin Murdoch

Sir Russell Brain was admitted to the honorary fellowship

The following were admitted to the fellowship

P C Barkla T S M Barnett F A Bellingham, N B Capon, Daphne Wai Chan Chun Alexander Culiner W D Cunningham, J P O Erskine, Mary Evans W R Foote F D Johnston K T Macfarlane T A Macfarlane, G B Maughan Daw Yin May W G Mills Kripananda Mitra J G O Donoghue H E Pellew Percy Peltz D A Ranasinghe W J Rawlings R M Rome D W Sparling Dorothy M Stewart James Walker J F B Wyper

Scottish Society of Anæsthetists

The executive council of this society for 1957–58 is as follows

President Dr Robert Lawrie vice president Dr R N Sinclair, hon secretary Dr M Shaw other members Dr H B Wilson Dr J Straton Dr J R Kyles Dr H Fairlie Dr A C Forrester Dr A W Raffan and Dr W Christie

The society's prize for the best paper submitted by a registrar has been awarded this year to Dr D B Scott

Royal College of Physicians of London

On June 3, the first day of the celebrations of the Harveian tercentenary the college is holding a memorial service at St Paul s Cathedral at noon The service is open to all who care to go

University of London

On Nov 22 Sir Charles Lovatt Evans, F.R S, will be among those on whom honorary degrees are conferred He will receive the degree of doctor of laws

At a recent examination the following were successful

D.P M—H R Alderton A A Bartholomew, D T F MacSorley C M B Pare A C R Skynner, H J Walton

The following have passed the final examination for the degrees of M B, B S

Sir James Walton Memorial

A library in memory of Sir James Walton has been installed in the committee room of the Gemmological Association The library contains some of the gemstones and gem minerals he collected and the gem testing instruments which he made

Hunterian Society

The subject for this society's 1957 essay competition is the Diagnosis and Management of Coronary Disease in General Practice The competition is open to all *general practitioners* Further details may be had from the hon secretary, Dr C W Kesson, 51, Harley Street, London, W 1

Experimental Research into Ageing

The trustees of the Ciba Foundation are offering in 1958 not less than five awards (£300 each) for investigations into the basic problems of ageing Entries must reach Dr G E W Wolstenholme, director of the foundation, 41, Portland Place, London, W 1, not later than Jan 1, 1958

World Federation for Mental Health

The annual meeting of this federation will be held this year at Copenhagen from Aug 11 to 17 The theme of the meeting will be Growing Up in a Changing World Further particulars may be had from the secretariat, 19, Manchester Street, London, W 1

Biology of Hair Growth

The British Society for Research on Ageing is to hold a symposium on this subject at 1, *Wimpole Street, London*, W 1, from Aug 7 to 9 under the chairmanship of Prof William Montagna Further particulars may be had from Mr G H Bourne, D SC, histology department, London Hospital, E 1

Banting Memorial Meeting

This meeting, which is organised by the British Diabetic Association, will be held in Oxford on Friday and Saturday, July 12 and 13 Prof H A Krebs, F R S, will give the Banting lecture, on intermediary metabolism in the diabetic organism, and *Prof C H Best*, F R S, will speak on oral hypoglycæmic agents The full programme may be had from the secretary general of the association, 152, Harley Street, London, W 1

Flour and Bread

The Nutrition Society is holding a symposium on this subject in the Anatomy School, Cambridge, on Friday and *Saturday, July 5 and 6*, under the *chairmanship of Sir Rudolph* Peters, F R S The speakers will include Dame Harriette Chick, D SC, Miss E M Widdowson, D SC, Prof R A Morton, F R S, Dr H M Sinclair, and Mr J R Nicholls, D SC Further particulars may be had from Miss D F Hollingsworth, c/o Ministry of Agriculture, Fisheries, and Food, Great Westminster House, Horseferry Road, London, S W 1

National League of Hospital Friends

Mr Dennis Vosper, the Minister of Health, speaking on May 24, at the annual meeting of this league, said that he would like every hospital to have its own special group of supporters Hitherto mental and mental deficiency hospitals had not been nearly so well befriended, but he was now glad to see that there had been exceptional progress in the formation of leagues of friends of mental hospitals Nothing could be more important because these hospitals were so often situated in old buildings, designed for another age in mental health, and located in remote districts Those who do work in association with mental hospitals would be aware of the enormous change in attitude and treatment which had taken place during recent years It must be our aim to convince the public that they should look upon a mental hospital as upon an ordinary hospital for the physically sick and he was sure that an active League of Friends could help towards breaking down remaining barriers Many people, he added, thought that with the advent of the National Health Service in 1948 voluntary work was no longer wanted in the hospitals of this country He did not believe that attitude was ever adopted by those in any way associated with the hospitals, and there could be nothing but tragedy if this should ever come to pass Perhaps it was not as widely known as it should be that in the past few years there had not been a decrease in voluntary work for hospitals but a most startling and welcome increase " Although the League of Hospital Friends are not mentioned by name in any Act of Parliament I, like my predecessors, regard them as essential partners in the health service '

Tuberculosis Conference in Glasgow

The British Tuberculosis Association and the Tuberculosis Society of Scotland are holding their annual conference in Glasgow from June 26 to 29 Further particulars may be had from the administrative secretary of the association, 59, Portland Place, London, W 1

Reciprocal Benefits

A convention on social security between the United Kingdom and Belgium has been signed It covers benefits for sickness, maternity, death, unemployment, old age, widowhood, orphanhood, and industrial accidents and diseases, and family allowances It will not come into operation until it has been ratified by both Governments

Calvert Memorial

On May 23 Sir Geoffrey Jefferson, F R S, unveiled a portrait of the late Cecil Calvert which his *medical colleagues on the* staff of the Royal Victoria Hospital, Belfast, are giving to the hospital In accepting it Mr Victor Clarendon, the chairman, announced that the hospital committee are to set up, from their "free funds," a Cecil Calvert research scholarship

Control of Chemical Additives in Food

This subject will be discussed at a joint meeting of the Food Law Institute of the United States and the food group of the Society of Chemical Industry, the Society for Analytical *Chemistry*, and the Association of Public Analysts, *to be held* at the Royal Institution, London, on Friday, July 26 at 10 A M Further particulars may be had from the office of the Society for Analytical Chemistry, 14, Belgrave Square, S W 1

Therapeutic Substances Act, 1956

By regulation, novobiocin, oleandomycin, spiramycin, prednisone, and prednisolone have been brought under the control of part II of this Act and from June 1 their sale and supply will be restricted

Since the provisions of part II of the Act apply to any preparation which contains a controlled substance, it appears *that the sale and supply of ' Sigmamycin,'* which is understood *to be a mixture* of tetracycline and oleandomycin, are subject to control

Latency and Masking in Viral and Rickettsial Infections

From Sept 4 *to* 6 the University of Wisconsin School of Medicine is holding a *symposium* on this subject to consider recent information on human, animal, and plant systems that bear on the interaction between host cell, infecting agent and the cellular environment The speakers from England will include Dr C H Andrewes, F R S, and Mr F C Bawden, F R S Further particulars may be had from Dr A S Evans division of preventive *medicine*, University of Wisconsin Medical School, Madison, Wisconsin, U S A

L C C Child-guidance Clinics

Besides using 20 hospital and other child guidance clinics the London County Council has established four child guidance units—at Earls Court, Battersea, Brixton, and Woodberry Down A report presented to the Education Committee on May 20 says that, during 1956, 516 applications were received for reference to these four units, and at the end of the year 130 children were awaiting a first interview and 63 had been interviewed and awaited treatment Though very urgent cases can usually be seen within two or three weeks, the waiting period for other cases is two to three months *for interview and* between three and eight months for treatment *After consultation* with the regional boards which provide the *medical staff* (but not the psychologists and psychiatric social workers) it is proposed that from Sept 1 the *unit at Earls Court* shall be *expanded and that a new unit shall be established at Queen's* Road Centre, Peckham, to serve part of south east *London*

Dr Hirotoshi Hashimoto president of St Luke's International Hospital Tokyo Mr Yoshisuke Kasai vice president of the Japanese Red Cross Society Mr *Toshikatsu Kuraki* chief of the planning section at the ministry of health and welfare and Dr Nobuo [illegible] assistant chief of the tuberculosis prevention section of the ministry are spending ten days in Britain studying the National Health Service in a programme organised by the British Council

---

CORRIGENDUM *Wilson's Disease*—In the letter by Dr Hall and Dr Neale last week (p 1089), the last *sentence* of the first paragraph should have begun ' *Indeed*, balance studies in three of our patients ' We regret that we wrongly inserted "untreated" The authors stress that none of the balance studies was done during a period of active copper-removing therapy

PROGNOSTIC FACTORS IN MYOCARDIAL INFARCTION

G. E. Honey

ASSISTANT PHYSICIAN, NUFFIELD DEPARTMENT OF CLINICAL MEDICINE, UNIVERSITY OF OXFORD

From the Radcliffe Infirmary, Oxford

Since the early reports by Obrastzow and Straschesko (1910), Herrick (1912, 1919), McNee (1925), and Gibson (1925), coronary thrombosis has become well recognised, and it now ranks as one of the more common causes for emergency admission to hospital. Probably the condition has truly become much commoner, but nowadays one reason for admission to hospital in many cases of this condition is the development of treatment with anticoagulants—a form of therapy best controlled in hospital.

We need to know whether the prognosis of this dangerous illness has been much changed by the use of anticoagulant therapy, and to define other factors which have a bearing on either the immediate or the long term prognosis. These questions are examined in the present study.

TABLE I—ANNUAL ADMISSIONS FOR CORONARY THROMBOSIS

Treatment-period	Year	No. of admissions	Total for period	Percentage treated with anti coagulants
I	1940	8	110	0·0
	1941	11		
	1942	7		
	1943	14		
	1944	18		
	1945	18		
	1946	15		
	1947	19		
II	1948	29	170	37·1
	1949	29		
	1950	51		
	1951	61		
III	1952	81	263	74·5
	1953	87		
	1954	95		
Total			543	

SOURCES OF DATA

The case notes of all patients with myocardial infarction admitted to the Radcliffe Infirmary in 1940–54 inclusive were analysed, together with those of a much smaller number of patients who developed the disease while in the hospital for other reasons. Only patients in whom there was no reasonable doubt about the diagnosis were included. In all cases the diagnosis was supported by electrocardiographic or necropsy evidence. A comparatively small number of patients who were admitted late in the illness (for example, because of congestive cardiac failure due to myocardial infarction two or three weeks earlier) were excluded in order to keep the clinical material as homogeneous as possible. After these exclusions, there were 543 admissions available for analysis. Some patients were admitted more than once and the number of patients was 506. We have chosen to treat each episode as a separate entity.

We have taken the arbitrary period of two months (eight weeks) as representing the acute attack. The subsequent fate of patients who survived the acute attack was discovered in all cases, except for a man who was admitted to the Radcliffe Infirmary in 1950 and was known to be alive in 1953, but whom we were unable to trace subsequently. With this solitary exception, it is known whether each patient was alive or dead when this study closed in January, 1956, and, if dead, the date of death and the certified cause. We are glad to express our thanks for information supplied by other hospitals and by family doctors. The patients themselves, their relatives, and their friends have all been very cooperative. The Registrar-General has been a valuable source of information. From the data obtained in these various ways, factors affecting long-term prognosis were assessed.

TABLE II—THE DAILY NUMBER OF DEATHS DURING THE ACUTE ATTACK

Time	No. of deaths	Average daily deaths
1st day	62	62
2nd day	13	13
Rest of 1st week	42	8·4
2nd week	35	5·0
3rd week	16	2·3
4th week	7	1·0
5th week	5	0·7
6th week	6	0·9
Rest of 2nd month	9	0·5
Total	195	

There were certain advantages in making this study in the Radcliffe Infirmary:

(*a*) It is the only general hospital admitting emergencies from the city of Oxford and a surrounding rural district.

(*b*) It is the main teaching hospital of the University of Oxford, the case notes are well kept and there is an efficient records department.

(*c*) The laboratory estimations on which the control of anticoagulant therapy is based are done under the direction of pathologists who are authorities on blood coagulation (Biggs and Macfarlane 1953).

PROGNOSIS IN THE ACUTE ATTACK

During the period under review, the annual number of admissions to hospital increased progressively, the chief rise being between 1947 and 1952, when anticoagulants began to enjoy a vogue in treatment. Before 1948 no patient was treated in the Radcliffe Infirmary with anticoagulants. In 1948, 4 patients out of 29 admitted were so treated, and in 1951, 36 out of 61 admitted. Since 1951, 3 out of every 4 patients have been treated with anticoagulants, and there has been little change from year to year. Throughout the hospital it has been usual to treat patients with anticoagulants unless there were contra-indications. We can therefore define three treatment-periods—1940–47, 1948–51, and 1952–54 (table I).

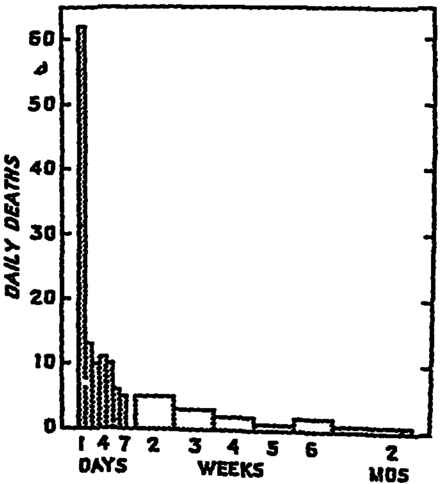

Fig. 1—Number of deaths during acute attack among 543 admissions. After first week numbers are expressed as average daily rate.

When bigger numbers of patients are admitted at the same time as a new treatment is coming into regular use, any results must be interpreted cautiously. A seeming improvement in prognosis may be attributed to the new

TABLE III—FATALITY RATE IN ACUTE ATTACK BY AGE AND SEX

Age (yr)	Men			Women		
	No of patients	Deaths		No of patients	Deaths	
		No	%		No	%
<40	10	1	10 0	0	0	0 0
40–	56	18	32 1	15	3	20 0
50–	119	37	31 1	30	8	26 7
60–	118	38	32 2	61	24	39 3
70–	57	31	54 1	58	21	36 2
80–	12	10	83 3	7	4	57 1
Totals	372	135	36 3	171	60	35 1

therapy when in fact it is due to the admission of less severe cases In making the analysis, we have therefore kept separate the groups of patients who were admitted in the three main periods of time, and have further subdivided them according to whether or not anticoagulants were used In presenting the results we have often fused these subgroups in the interests of brevity, but only after satisfying ourselves that no distortion is caused by so doing

Death in the Acute Attack

Among the 543 admissions, there were 195 deaths (34 9%) within two months of admission (table II) The outstanding feature is the high fatality during the first day, followed by a progressive fall in the average daily deaths until the end of the fourth week, when the curve of deaths flattens out and runs at a low level (fig 1) No less than a third of all the deaths in the acute attack took place on the first day in hospital The danger of this first twenty four hours is emphasised by the realisation that 1 patient in every 9 admitted died within this period This reflects the fact that the Radcliffe Infirmary receives a large proportion of its patients as acute emergencies soon after the actual infarction (The results obtained in different hospitals are difficult to compare because of differences in the proportion of patients admitted in the earliest and most dangerous stage of the disease)

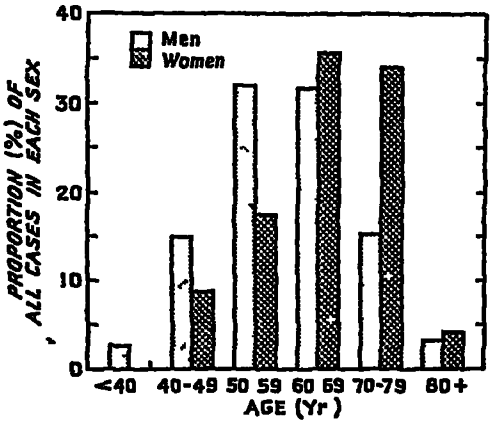

Fig 2—Percentage distribution of all cases in each sex by age

TABLE IV—FATALITY RATES IN FIRST AND SUBSEQUENT ATTACKS

—	No of patients	Deaths	
		No	%
First attack	455	170	37 4
Second or later attack	88	25	28 4

Early Deaths

In view of the large number of deaths soon after admission to hospital, it is convenient to separate off the deaths in the first forty-eight hours from the later deaths For several reasons, we have chosen the period of forty eight hours to cover what we shall refer to as "early deaths"

First, it is sometimes difficult to decide from the case notes whether a patient died exactly within twenty four hours or not, so that a small error arises from this "fringe effect", the error is less if the division is made at forty eight hours

Secondly, when considering the usefulness of anticoagulants, it is convenient to be able to eliminate the deaths in the first forty eight hours, to give a reasonable length of time for the treatment to be instituted and become effective

All deaths later than forty eight hours after admission have been called "late deaths"

Factors Affecting Prognosis in the Acute Attack

Age and sex—Coronary thrombosis is much commoner in men than in women, and there were more than twice as many men as women in this series (table III) On average, the condition arose in women at a later age than in men (fig 2) Two thirds of the men were admitted between the ages of 50 and 70, and two thirds of the women between the ages of 60 and 80 In each sex, the fatality increased with advancing years, but in each age group women tended to have a lower fatality rate than men (fig 3) There were therefore two opposing influences affecting the fatality rate by sex the women included a greater proportion of elderly subjects who were more liable to die, but in all age groups but one the women had a better chance of survival than the men These two processes counteracted one another so evenly that the net result was an almost exactly equal fatality-rate for men and women Because of this, in many of the succeeding sections the patients are treated as a whole

TABLE V—FATALITY RATE IN ACUTE ATTACK IN RELATION TO HISTORY OF ANGINA OF EFFORT

History of angina	No of patients	Deaths	
		No	%
Positive	217	81	37 3
Negative	326	114	35 0

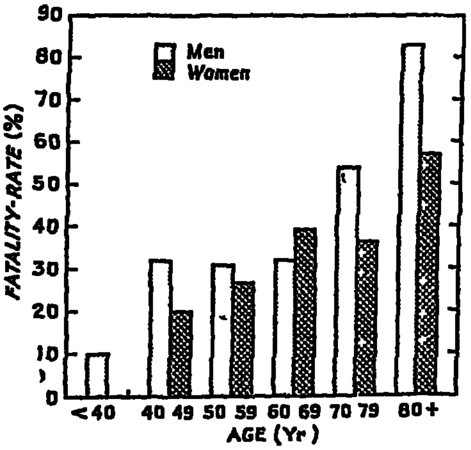

Fig 3—Fatality rates by age and sex

History of a Previous Attack

It is commonly held that a second or subsequent attack is more dangerous than the first attack of myocardial

TABLE VI—PRE-EXISTING HYPERTENSION RELATED TO FATALITY RATE IN THE ACUTE ATTACK

History of previous hypertension	No of patients	Deaths	
		No	%
Positive	180	57	31 7
Negative	363	138	38 0

TABLE VII—PREVIOUS BREATHLESSNESS ON EXERTION RELATED TO FATALITY-RATE IN THE ACUTE ATTACK

History of breathlessness on exertion	No of patients	Deaths	
		No	%
Positive	196	69	35 2
Negative	347	126	36 3

TABLE VIII—FATALITY-RATES AMONG PATIENTS DEVELOPING CORONARY THROMBOSIS AT REST AND ON EXERTION

Mode of onset	No of patients	Deaths	
		No	%
At rest	296	102	34 5
On exertion	181	54	29 8

infarction In 88 admissions in the present series there was a clear-cut history of a previous attack—treated at the Radcliffe Infirmary in 37 cases and elsewhere in 51 There was no appreciable difference in the mortality-rate between these 88 patients and those admitted in their first episode (table IV)

Previous Angina of Effort

No less than 40% of the patients had a history of angina of effort The two sexes were almost identical in this respect We have not counted angina of effort noticed for the first time in the ten days preceding the frank infarction leading to admission, for this may be a prodroma to the infarction In neither sex was the fatality-rate affected by a history of angina of effort (table V)

TABLE IX—SHOCK AND HYPOTENSION RELATED TO DEATHS IN THE ACUTE ATTACK (I.E, IN FIRST TWO MONTHS)

Shock and hypotension	No of patients	Deaths	
		No	%
Both	41	26	63 4
Shock alone	50	23	46 0
Hypotension alone	21	11	52 4
Neither	431	135	31 3

TABLE X—EARLY DEATHS (I E, IN FIRST FORTY EIGHT HOURS) RELATED TO SHOCK AND HYPOTENSION

Shock and hypotension	No of patients	Early deaths	
		No	%
Both	41	22	53 7
Shock alone	50	12	24 0
Hypotension alone	21	5	23 8
Neither	431	36	8 4

Previous Hypertension

A third of the patients were known to have been hypertensive before the onset of myocardial infarction By hypertension we imply a systolic pressure of more than 160 and a diastolic pressure of more than 100 mm Hg Hypertension was commoner among women patients (41 5%) than among men (29 3%)—a difference which is significant The fatality rate was unaffected by pre existing hypertension (table VI)

Previous Breathlessness on Exertion

More than a third of the patients had been breathless on exertion for at least some months This, too, had no effect on the fatality rate (table VII) There was no appreciable difference in mortality here between men and women

Mode of Onset of Infarction

It is often taught that coronary thrombosis usually begins when the patient is at rest In this series the circumstances of the onset were clearly specified in 477 instances In 181 of these, the infarction occurred during exertion, this made little difference to the outcome (table VIII) The proportion of cases in which the infarction developed during exertion was the same in men and in women

Shock and Hypotension

If patients arrived at hospital in a state of clinical shock or with hypotension, their prognosis was much worse than if they had neither We have accepted the statement of the admitting doctor that "shock" was present or absent, by hypotension is meant a systolic blood-pressure of less than 100 mm Hg In many cases these two features were combined, and the outlook was then even worse, nearly two-thirds of such patients dying (table IX)

TABLE XI—LATE DEATHS (BETWEEN FORTY-EIGHT HOURS AND TWO MONTHS AFTER ADMISSION) RELATED TO SHOCK AND HYPOTENSION ON ADMISSION

Shock and/or hypotension	No of patients	Deaths	
		No	%
Present	73	21	28 8
Absent	395	99	25 1

TABLE XII—LATE DEATHS (FORTY-EIGHT HOURS TO TWO MONTHS) RELATED TO DIABETES MELLITUS

Diabetes mellitus	No of patients	Deaths	
		No	%
Present	37	19	51 4
Absent	431	101	23 4

The increased fatality among patients admitted with shock or hypotension occurred solely in the first forty-eight hours (table X), the survivors of this period having the same prognosis thereafter as other patients (table XI, fig 4)

Diabetes Mellitus

Diabetic patients with myocardial infarction did badly The surplus of deaths among diabetics was solely among the late deaths (table XII)

History of Cardiac Asthma

A history of cardiac asthma had a bad prognostic significance—an effect almost confined to the late deaths (table XIII)

Evidence of Cardiac Failure

Any evidence of cardiac failure had a bad prognostic significance, for half of the patients with such evidence died The effect was almost confined to the late deaths, and was much the same whether the failure was of the right side or the left side of the heart (table XIV)

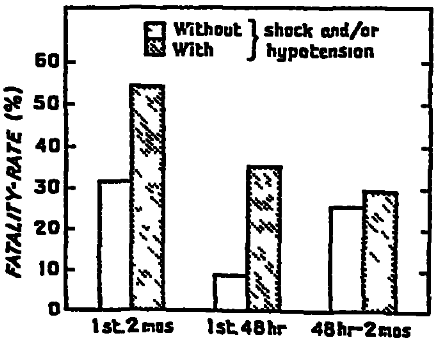

Fig 4—Fatality-rates in acute attack according to presence or absence of shock and/or hypertension

Arrhythmias

Cardiac arrhythmias were also of bad prognostic import, though not as serious as evidence of heart failure, the effect was confined to the late deaths

TABLE XIII—LATE DEATHS (FORTY-EIGHT HOURS TO TWO MONTHS) RELATED TO PREVIOUS HISTORY OF CARDIAC ASTHMA

Previous cardiac asthma	No of patients	Deaths	
		No	%
Present	26	10	38·5
Absent	442	110	24·9

TABLE XIV—LATE DEATHS (FORTY-EIGHT HOURS TO TWO MONTHS) RELATED TO EVIDENCE OF CARDIAC FAILURE

Heart failure	No of patients	Late deaths	
		No	%
Nil	325	61	18·8
Right sided	61	25	41·0
Left sided	82	34	41·5

(table xv) 17% of all admissions were complicated by arrhythmia Heart-block and ventricular tachycardia were unusual Multiple extrasystoles and auricular fibrillation or flutter were roughly equally common, and their prognostic significance also was equal Excluding deaths in the first forty-eight hours, of 38 patients with multiple extrasystoles 14 died (36·8%), while of 39 patients with auricular fibrillation or flutter 15 died (38·5%)

Cardiomegaly

The size of the heart was definitely stated in 307 cases If we take these as being reasonably representative, patients with gross cardiac enlargement (found clinically or radiologically) had a worse prognosis than those with hearts of normal size or only slightly enlarged The effect falls chiefly on the late deaths (table xvi)

Good risk and Bad risk Patients

We can define two groups of patients—a "good-risk" group who show none of the factors included in the left-hand column of table xvii, and a "bad-risk" group in which one or more of these factors is present (table xviii, fig. 5)

TABLE XV—RELATION BETWEEN CARDIAC RHYTHM AND LATE DEATHS (FORTY-EIGHT HOURS TO TWO MONTHS)

Cardiac rhythm	No of patients	Deaths	
		No	%
Sinus rhythm	385	89	23·1
Arrhythmia	83	31	37·3

TABLE XVI—RELATION BETWEEN HEART SIZE AND LATE DEATHS (FORTY EIGHT HOURS TO TWO MONTHS)

Heart size	No of patients	Deaths	
		No	%
Normal or sl enlarged	241	48	19·9
Grossly enlarged	48	16	33·3

Effect of Age on Prognosis in Relation to Good and Bad Risk

In an earlier section it was shown that the older age-groups were more prone to die than the younger In good-risk patients the fatality-rate increased with advancing age, whereas in bad-risk patients the fatality rate was not much influenced by age, being remarkably constant until the age of 70 This is equally true for total deaths and for deaths after the first forty eight hours (tables xix and xx, fig 6)

The proportion of good-risk patients was highest in the younger age groups (table xxi) Taking the series as a whole, the younger age groups had a better prognosis for two reasons

(*a*) They contained a bigger proportion of good risk patients

(*b*) The good risk cases had a better prognosis in the younger age groups

Effect of Anticoagulant Therapy

During the period covered by the present series, the outstanding change in therapy was the introduction of anticoagulants, which were being widely used during the closing years of this study It has been generally accepted that anticoagulants exert a highly beneficial effect on the course of myocardial infarction, and direct comparison of the patients in the present series who were treated with anticoagulants with those who were not so treated suggests that anticoagulants have substantially lowered the fatality-rate (table xxii) But when patients have not been allocated at random to one form of therapy or another, the results may be biased by selection in the choice of patients for treatment In the present series there is strong evidence that such bias has been introduced Tables xxiii and xxiv and figs 7 and 8 set out the fatality-rates for the three treatment periods and in relation to treatment Taking period i (when no anticoagulants were used) as the starting-point, the fatality-rates in periods ii and iii fall progressively among the patients treated with anticoagulants, *but rise progressively among the patients not so treated* The only likely explanation is that the patients not given anticoagulants included an increasingly high proportion with a bad prognosis Any direct comparison between the patients treated with anticoagulants and those not so treated is therefore invalid

With our present data, the nearest we can get to a fair assessment of the effects of anticoagulant therapy is to present the overall results for the three periods, which will show the net effect of the introduction and subsequent extensive use of anticoagulant therapy There has been some improvement in the overall fatality rate in period iii when anticoagulants were being extensively used (table xxv, figs 9 and 10), and the effect is entirely in the late deaths There is therefore prima facie evidence that anticoagulants have been beneficial, but the fatality rate remains substantial and even the improvement in late deaths is not statistically significant

Moreover, the composition of the three period groups must be considered, especially in relation to those factors

TABLE XVII—FACTORS ASSOCIATED WITH BAD PROGNOSIS IN THE ACUTE ATTACK

Factors associated with bad prognosis	Factors unassociated with bad prognosis
Associated with early deaths	Previous attack of myocardial infarction
Clinical shock on admission	Previous angina of effort
Hypotension on admission	Previous breathlessness on exertion
Associated with late deaths	Previous hypertension
History of cardiac asthma	Mode of onset of infarction (at rest or on exertion)
Cardiac failure	
Arrhythmias	
Gross cardiac enlargement	
Diabetes mellitus	

TABLE XVIII—DEATHS AMONG GOOD RISK AND BAD RISK PATIENTS

Group	Total deaths			Late deaths (early deaths excluded)		
	No of patients	Deaths		No of patients	Deaths	
		No	%		No	%
Good risk	152	26	17·1	142	16	11·3
Bad risk	391	169	43·2	326	104	31·9

which we have demonstrated as having an influence on prognosis. The three period-groups were closely similar in respect of the proportion of patients with recurrent attacks, previous hypertension, angina of effort, and breathlessness on exertion. The age-composition was also closely similar. With respect to the bad prognostic factors, the general picture is best seen from the proportion of good-risk patients in the various periods. Period III had the highest proportion of patients falling in the good-risk class (table XXVI).

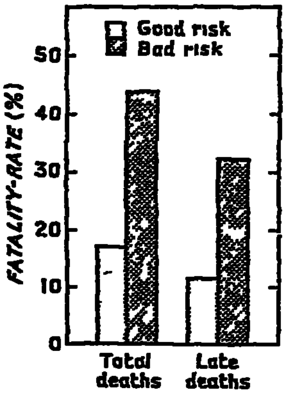

Fig 5—Fatality-rates in acute attack of good risk and bad-risk groups

This fact alone would account for some of the improvement in prognosis in period III. Whether it accounts for it fully can be seen by constructing a table in which the fatality-rates observed for good-risk and bad-risk cases in period I are used as the standard by which "expected" deaths are calculated for periods II and III (table XXVII). There were only 86 deaths in period III instead of the 96 which would be expected from the number of good-risk cases if anticoagulants had no effect, so some true improvement can be said to have taken place. The proportion of patients dying within forty-eight hours after admission was closely similar in periods I and III, so the improvement over expected values is to be found among the late deaths.

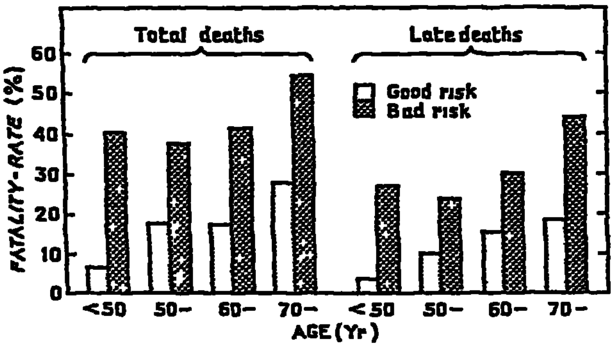

Fig 6—Fatality rates in acute attack among good risk and bad-risk cases related to age

We have made a further calculation on slightly different lines. From the total series, age-specific fatality-rates can be calculated for both good risk and bad-risk cases (tables XIX and XX). Then, for each period, the expected number of deaths can be estimated while taking account simultaneously of the number of good-risk and bad-risk cases in each age group. In effect, one is making a "null hypothesis" with respect to treatment and setting out the expected fatality rates on the assumption that treatment has not materially changed in efficacy and the only prognostic factors which matter are the age and numbers of good-risk and bad-risk cases in the successive periods. If anticoagulant treatment has revolutionised the outlook in the acute attack, the observed fatality-rates should differ sharply from expected rates, being worse than expected before the onset of anticoagulant therapy and better than expected after it was widely used. In fact there are some differences in these directions between observed and expected rates, but they are not large (table XXVIII). In other words, the data in table XXVIII agree with those in table XXVII in suggesting that anticoagulants have had only a small beneficial effect on the fatality of myocardial infarction in this hospital. The total saving of lives in period III, when anticoagulants were extensively used, was of the order of 10 lives out of 263 admissions.

TABLE XIX—TOTAL DEATHS RELATED TO AGE IN GOOD AND BAD-RISK GROUPS

Age (yr)	Good risk			Bad risk		
	No of patients	Deaths		No of patients	Deaths	
		No	%		No	%
<50	31	2	6.5	50	20	40.0
50–	56	10	17.9	93	35	37.6
60–	40	7	17.5	139	57	41.0
70–	25	7	28.0	109	59	54.1

TABLE XX—LATE DEATHS RELATED TO AGE IN GOOD- AND AND BAD-RISK GROUPS (EARLY DEATHS EXCLUDED)

Age (yr)	Good risk			Bad risk		
	No of patients	Deaths		No of patients	Deaths	
		No	%		No	%
<50	30	1	3.3	41	11	26.8
50–	51	5	9.8	76	18	23.7
60–	39	6	15.4	120	36	30.0
70–	22	4	18.2	89	39	43.8

TABLE XXI—PROPORTION OF GOOD RISK CASES IN EACH AGE GROUP

Age (yr)	No of cases	Good risk cases	
		No	%
<50	81	31	38.3
50–	149	56	37.6
60–	179	40	22.3
70–	134	25	18.7
Total	543	152	28.0

In view of this, it is of interest to examine the causes of death in the successive treatment-periods. The proportion of fatal cases examined at necropsy was about 70% in all periods. From a detailed examination of the necropsy reports, the salient point emerges that the widespread use of anticoagulants has been accompanied by a striking reduction in the number of deaths from pulmonary embolism. In other respects, there was no obvious difference in the immediate causes of death in the three treatment-periods.

TABLE XXII—DIRECT COMPARISON OF PATIENTS TREATED WITH ANTICOAGULANTS WITH PATIENTS NOT SO TREATED

Anticoagulants	Total deaths			Late deaths		
	No of patients	Deaths		No of patients	Deaths	
		No	%		No	%
Given	259	59	22.8	239	39	16.3
Not given	284	136	47.9	229	81	35.4

Before anticoagulant therapy became generally used, about 6% of the patients surviving the first forty-eight hours died from pulmonary embolism, whereas in the latest treatment-period only about 1% did so (table XXIX).

The final column of table XXIX shows estimated figures based on the assumption that the patients examined at necropsy were an unselected sample of the late deaths; we believe this assumption to be sound, because the usual reason for an absence of necropsy was that the relatives refused permission.

TABLE XXIII—TOTAL DEATHS RELATED TO TREATMENT-PERIOD AND USE OF ANTICOAGULANTS

Period	Patients given anticoagulants (%)	With anticoagulants			Without anticoagulants		
		No of patients	Deaths		No of patients	Deaths	
			No	%		No	%
I (1940–47)	0				110	44	40.0
II (1948–51)	37.1	63	17	27.0	107	48	44.9
III (1952–54)	74.5	196	42	21.4	67	44	65.7

The use of anticoagulant therapy has therefore saved about 11 lives which would otherwise have been lost through pulmonary embolism About 10 fewer patients died in period III than one might have expected from what had happened in period I The similarity between this improvement and the saving of life by protection from pulmonary embolism makes us conclude that the only substantial effect of anticoagulant therapy is to prevent death from pulmonary embolism

TABLE XXIV—LATE DEATHS RELATED TO TREATMENT-PERIOD AND USE OF ANTICOAGULANTS (EARLY DEATHS EXCLUDED)

Period	Patients given anticoagulants (%)	With anticoagulants			Without anticoagulants		
		No of patients	Deaths		No of patients	Deaths	
			No	%		No	%
I (1940–47)	0				92	26	28.3
II (1948–51)	39.5	60	14	23.3	92	33	35.9
III (1952–54)	79.9	179	25	14.0	45	22	48.9

Discussion

The most arresting feature of the present study has been the finding that extensive use of anticoagulant therapy has not made a dramatic difference to the fatality rate of myocardial infarction in this hospital It is true that some improvement has taken place since this form of therapy was introduced, but this can be accounted for by the nearly complete abolition of death due to pulmonary embolism There seems little doubt that anticoagulants are very effective in this respect The success of anticoagulant therapy in preventing pulmonary embolism is evidence that this form of treatment was being effectively administered in this hospital We therefore conclude that anticoagulants do not have any major influence upon the course of an established myocardial infarct per se, although they save some lives by removing almost completely the dangerous complication of pulmonary embolism

This conclusion does not go as far in support of anticoagulant therapy as that of its more enthusiastic advocates For example, Wright et al (1948, 1950, 1954) claimed that anticoagulant therapy with dicoumarol produced a significant reduction in fatality during the acute attack Their opinions have been widely acclaimed, for they are based on the results of a large scale therapeutic trial carried out under the ægis of the American Heart Association At first glance their results appear impressive, for the fatality among those treated with anticoagulants was 16%, as against 23% for a control group not receiving this treatment But there are certain disturbing elements in the design and conduct of their trial

TABLE XXV—OVERALL FATALITY-RATES IN THE THREE TREATMENT PERIODS

Period	Total deaths			Late deaths		
	No of patients	Deaths		No of patients	Deaths	
		No	%		No	%
I	110	44	40.0	92	26	28.3
II	170	65	38.2	152	47	30.9
III	263	86	32.7	224	47	21.0

The most important criticism is that it was laid down that patients admitted on an odd day of the month would be treated with anticoagulants, whereas those admitted on even days would not It should be a cardinal rule in any controlled therapeutic trial that a patient should first be selected as suitable for admission into the trial and then be allotted at random to one or other forms of treatment Any failure to insist on this creates the opportunity for bias In the case of Wright et al 's trial, the number of treated patients was considerably greater than the number of controls, the numbers being 580 and 442 respectively There are, of course, a few more odd days of the month than even days in the course of a year, but not nearly enough to account for this big disparity in numbers between the two groups Indeed, even allowing for the extra number of odd days in a year, such a big surplus of treated cases would happen by chance less than one in a thousand times, so we can take it that bias has entered into the allocation of treatment The authors themselves admit that, as the trial progressed, some patients were being put into the treatment group at the express wish of their relatives or private physicians

Tulloch and Gilchrist (1950) also presented evidence that anticoagulants were highly

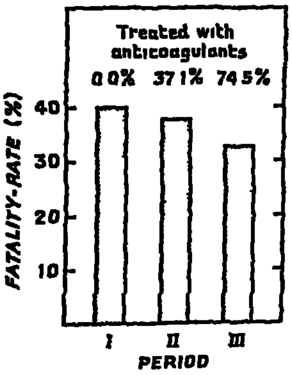

Fig 9—Overall fatality rates in acute attack in each period

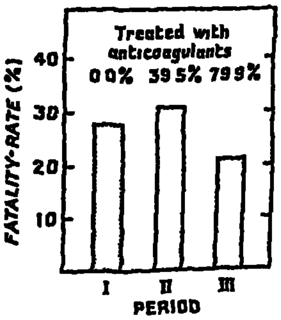

Fig 10—Fatality rates in acute attack, with early deaths excluded, in each period

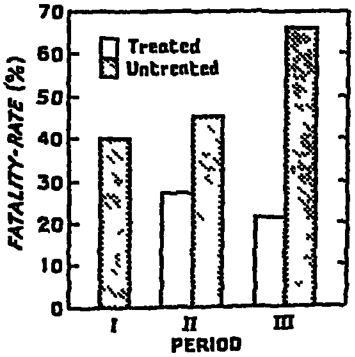

Fig 7—Fatality-rates in various treatment periods related to treatment with anticoagulants

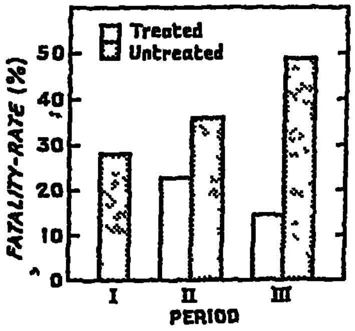

Fig 8—Fatality rates in acute attack, excluding early deaths, according to period and treatment with anticoagulants

TABLE XXVI—PROPORTION OF GOOD RISK PATIENTS IN EACH TREATMENT-PERIOD

Period	No of patients	Good risk patients	
		No	%
I	110	27	24·5
II	170	38	22·4
III	263	87	33·1

beneficial in myocardial infarction, those treated having a fatality-rate of 22·8%, as against 40·5% for the control group

Some of their patients were not given anticoagulant therapy because of some contra indication, but they do not mention whether equivalent patients were excluded from the control group In fact, their control group was larger than the treated group, and this may have been due to a failure to exclude similar patients from each group Our own data show that patients not treated with anticoagulants at a time when this form of therapy had become generally accepted had a very bad prognosis—considerably worse than the overall figure for the pre anticoagulant era In other words, if Tulloch and Gilchrist removed patients with a bad prognosis from their treated group and failed to remove similar patients from their control group, this would inevitably exaggerate the beneficial effects of anticoagulant therapy

A later paper by Gilchrist (1952) is open to more stringent criticism, for in this he has made a direct comparison of patients treated with and without anti coagulants over a period which begins well before the introduction of this therapy, passes through the "controlled" stage of 1947–49, and extends into 1951 when anticoagulants were being generally used except when specific contra-indications existed

TABLE XXVII—OBSERVED AND "EXPECTED" DEATHS IN THE PERIODS, USING PERIOD I AS THE STANDARD FOR CALCULATING EXPECTED DEATHS IN *GOOD-RISK AND BAD-RISK* CASES

Period	No of deaths	
	Observed	Expected
I	44	44
II	65	69·6
III	86	95·5

In effect, Gilchrist was comparing 87 patients treated with anticoagulants in 1950 and 1951 with 77 patients not so treated before 1947 But he does not mention how many patients were unfit for anticoagulant therapy, and in our data (tables XXIII and XXIV, figs 7 and 8) such patients had a bad prognosis By eliminating them from the period 1950–51, Gilchrist was bound to show an improvement even if anticoagulants had done nothing Thus selection of cases probably exaggerated the beneficial effects of anticoagulant therapy

TABLE XXVIII—OBSERVED AND EXPECTED DEATHS IN EACH TREATMENT-PERIOD

Period	Total deaths			Late deaths		
	No of patients	Observed deaths	Expected deaths*	No of Patients	Observed deaths	Expected deaths*
I	110	44	40·4	92	26	23·5
II	170	65	64·9	152	47	41·7
III	263	86	92·6	224	47	54·7

* Calculated on the basis of the age-composition and the number of good risk and bad risk cases in each age group

TABLE XXIX—DEATHS FROM PULMONARY EMBOLISM IN THE THREE TREATMENT PERIODS (*EARLY DEATHS EXCLUDED*)

Period	Number of patients (excluding early deaths)	Percentage of patients dying after the first 48 hours examined at necropsy	Deaths from pulmonary embolism in necropsy material	Estimated fatality-rate (%) from pulmonary embolism
I	92	73·1	4	6·0
II	152	61·7	6	6·4
III	224	74·5	2	1·2

From our own hospital, Loudon et al (1953) presented the results for the period January, 1948, to May, 1952, when anticoagulants were coming into vogue By making a direct comparison of treated and untreated cases they found a highly beneficial effect from the use of anticoagulant therapy The period they took was almost the same as our treatment-period II (January, 1948, to December, 1951) Our own results show a highly significant difference between anticoagulant treated and non-treated patients (table XXII), but we have been able to show that most of this effect is due to bias in the selection of patients for anticoagulant therapy This became more obvious as time went by, and in our latest treatment-period (1952–54), after we had excluded early deaths, nearly 50% of the patients not receiving anticoagulants died—a figure far in excess of that seen in period I before anticoagulants were introduced into this hospital (table XXII)

Schilling (1950) has also advocated anticoagulant therapy

In his hospital in New York, one admitting service treated patients with anticoagulants and the other did not Patients treated with anticoagulants did much better than patients not treated, but he does not compare the overall results for the two services, which would have given the net effect of anticoagulant therapy and would have removed the almost inevitable bias which is created if patients unsuitable for this form of therapy are excluded from one group and not from another Moreover, the figures for the two groups added together are slightly worse than the overall figures for the hospital during the preceding four years when anticoagulants were not in use

When we look closely at the evidence that anticoagulants exert a major influence on the course of myocardial infarction, it becomes plain that this evidence is not strong enough to deter us from the conclusion that the sole beneficial effect of this therapy is to eliminate death due to pulmonary embolism

Summary

In 1940–54 there were 543 admissions to the Radcliffe Infirmary because of acute myocardial infarction

In the acute attack (the two months after admission) there were 195 deaths (34·9%)

A third of these deaths were on the first day Thereafter the rate of dying fell off progressively

The presence of shock or hypotension or both when the patient arrived at hospital was associated with enhanced risk of death within forty-eight hours of admission

Among patients who survived the first forty-eight hours, a different set of factors was associated with enhanced risk of death during the rest of the acute attack These were a history of cardiac asthma, evidence of cardiac failure (either left or right ventricular), cardiac arrhythmia (including multiple extrasystoles), gross cardiac enlargement, and diabetes mellitus

Factors which have sometimes been supposed to be associated with a bad prognosis had no obvious association of this sort in the present series These factors were a previous attack of myocardial infarction, previous angina of effort, previous breathlessness on exertion, and previous hypertension Prognosis was likewise unaffected whether the onset was with the patient at rest or during exertion

Anticoagulant therapy was first used in this hospital in 1948 and was in extensive use by 1952 The overall effect of anticoagulant therapy on the fatality-rate has not been very great, and the improvement can be accounted for by the almost complete abolition of deaths from pulmonary embolism

(To be concluded)

LEUKÆMIA*

RONALD BODLEY SCOTT
M.A., D.M. Oxfd, F.R.C.P.
PHYSICIAN TO H.M. THE QUEEN; PHYSICIAN TO
ST. BARTHOLOMEW'S HOSPITAL

CHRONIC LYMPHATIC LEUKÆMIA

THE two common forms of chronic leukæmia stand in sharp contrast: whereas the myeloid variety follows a stereotyped and constant pattern, the lymphatic may assume any one of a dozen disguises. There are differences too in their age and sex incidence and in their therapeutic response. In chronic myeloid leukæmia treatment may fairly be described as standardised, but, because of the vagaries of the disease itself and its frequent association with other maladies, the management of chronic lymphatic leukæmia demands high qualities of clinical judgment and therapeutic finesse.

Chronic lymphatic leukæmia can be defined only in descriptive terms. It is marked by proliferation of lymphoid cells throughout the blood-forming organs; the cellular elements are usually mature; in the lymph-nodes the proliferation is diffusely spread throughout the medulla, and the resemblance of each cell to its neighbour confers on the microscopic field an appearance of unrelieved monotony; destruction and infiltration of the stroma, the histological hall-marks of malignancy, are lacking (Robb Smith 1938). In many instances this lymphoid overgrowth is associated with a rising tide of lymphocytes in the peripheral blood, but in the early phases this epiphenomenon may be absent.

The difficulties of definition are of two kinds. First, the tissue changes described as characteristic of chronic lymphatic leukæmia may occur without the peripheral lymphocytosis which has often been regarded as a diagnostic sine qua non. Secondly, a great increase in the number of lymphocytes in the blood may be accompanied by tissue changes quite different from those of chronic lymphatic leukæmia.

When faced by the first situation, morbid anatomists have been accustomed to apply the label of "lymphosarcoma"; but, though some claim the ability to separate lymphatic leukæmia from lymphosarcoma without reference to the blood count, the majority believe it to be a distinction without a difference. In most instances the passage of time brings with it the typical blood picture of lymphatic leukæmia. Some would regard this sequence as deserving the title "lymphosarcoma cell leukæmia," but this term is as imprecise as it is inelegant (Hauswirth et al. 1948) and, if it must be used, should be reserved for the escape of primitive lymphoid elements into the blood stream which often marks the closing stages of reticulosarcoma.

The second source of confusion is the presence of a leukæmic blood picture with tissue changes other than those of leukæmia. This may occur in lymphoid follicular reticulosis (follicular lymphoblastoma) and in Hodgkin's disease. It is more easily understood in the first, where the cellular proliferation is lymphocytic, than in the second, where it is pleomorphic.

In recent years I have seen 3 examples of lymphoid follicular reticulosis accompanied by a leukæmic blood picture; it is a well recognised event and usually noted toward the close of the disease (Anday and Schmitz 1952). In one it appeared only in the terminal phase; in the second it was found when the patient first sought attention; and in the third it provided a transient episode during the course of the illness. In none was the leucocytosis in excess of 30,000 per c.mm., and in all of them the cells were large lymphoid elements of unusual appearance. Some workers would undoubtedly have called these cases lymphosarcoma cell leukæmia.

Several instances are recorded in which the tissue changes of Hodgkin's disease were accompanied by the blood picture of chronic lymphatic leukæmia (Gill and McCall 1943, Seife et al. 1951). I have seen one example of this curious combination in a male aged 56; at the initial blood count, twenty-eight months before his death, the lymphocytes amounted to 96% of 160,000 white cells per c.mm.

Thus the blood changes commonly regarded as pathognomonic of chronic lymphatic leukæmia may on occasion accompany tissue changes characteristic of some other disorder, and the tissue changes of chronic lymphatic leukæmia are at times unassociated with any alteration in the peripheral blood. Both these events are uncommon, and difficulties of diagnosis are not frequent.

Incidence

The general incidence of chronic lymphatic leukæmia was discussed in the first lecture; although statistical proof is lacking, most clinicians in this country would agree that it is the commonest type of leukæmia seen in practice today. It is likely that there has been a relatively greater increase in its incidence than in that of other types, for it was reported in 1929 that only 25 patients with this disease had been admitted to the wards of the London Hospital in the preceding sixteen years (Panton and Valentine 1929). There has always been a greater number of males affected than females, and, in the present series of 227 patients, males made up 67.4% and females 32.6%. These proportions may have changed in the past few decades: a small series collected in 1912–28 was composed of 80% males and 20% females (Panton and Valentine 1929); another, of about the same period, contained 74% males and 26% females (Minot and Isaacs 1924); and 137 cases collected between 1913 and 1947 were divided into 71.5% males and 28.5% females (Shimkin et al. 1953). There is some indication in these figures that the disease may be becoming more common in women.

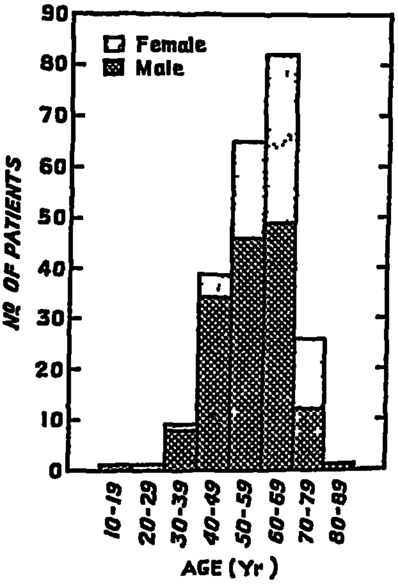

Fig. 9—Age at onset of symptoms in chronic lymphatic leukæmia.

In 80% of patients the first symptoms appeared between the ages of 40 and 70 (fig. 9). The mean age at onset for the whole series was 58.2, for males 56.0, and for females 62.8. There is little change in the overall mean from that of other published series, but for women the mean age of onset is some ten years older than in comparable collections of earlier date (Shimkin et al. 1953). This suggests that the increased incidence is particularly in elderly women.

Initial Physical Signs and Symptoms

The commonest reason for seeking medical advice is the chance discovery of enlarged lymph-nodes (fig. 10); this was the presenting complaint in 42.5% of the present

---

* The third Lettsomian lecture for 1957, delivered before the Medical Society of London on Feb. 18. The first two lectures were published on May 25 and June 1.

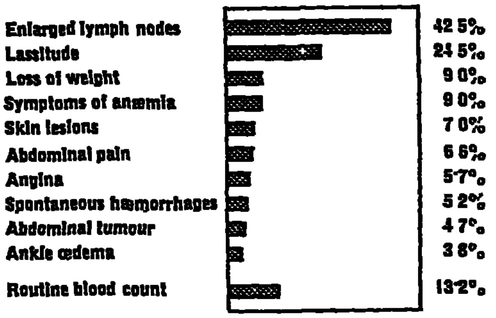

Fig 10—Presenting symptoms in 212 patients with chronic lymphatic leukæmia

series Next in order of frequency as an initial symptom was lassitude (24 2%), followed by loss of weight (9%), and symptoms of anæmia, such as dyspnœa (9 0%) A considerable proportion of patients (5 7%) complained of anginal pain, showing again how moderate anæmia will unmask myocardial ischæmia in the elderly Symptoms attributable to splenomegaly, so familiar in chronic myeloid leukæmia, are uncommon In only 6 6% was there abdominal pain, and only 4 7% had felt an abdominal tumour Œdema (3 8%) and spontaneous hæmorrhages (5 2%) were also rare

In a considerable proportion (13 2%) repeated infections brought the patient under observation This peculiar inability to withstand bacterial aggression is a feature of chronic lymphatic leukæmia and another point of distinction from the chronic myeloid variety It is a consequence of the immunological defect which marks the disease and of the long-recognised failure of its victims to produce antibodies on antigenic challenge (Howell 1920, Larson and Tomlinson 1953)

These recurrent infections are commonly of the respiratory tract, and the diagnosis is often first established when an attack of pneumonia or of purulent bronchitis brings the patient into hospital A smaller group have recurrent tonsillitis, in them considerable enlargement of the tonsils is usual. Repeated attacks of inflammation of unduly large tonsils in an elderly person should always arouse the suspicion of chronic lymphatic leukæmia In a still smaller number attacks of sinusitis furnish the overture to the disease

The other territory liable to bacterial invasion is the skin Impetigo, recurring cellulitis, and boils were all common initial complaints In addition to septic infection, however, other cutaneous lesions provide early symptoms In 3 these were specific leukæmic infiltrations (discussed below), but in 7 the illness began with an attack of herpes zoster This association is well recognised but remains unexplained (Gelfand 1951)

Finally, in 13 2% of this series the diagnosis of chronic lymphatic leukæmia was disclosed by a routine examination of the blood, usually because of some apparently unrelated illness Chance discovery of the disease in this way is increasingly common (Hougie 1956)

When the patient is first seen, the physical signs of the leukæmia fall into one of five categories (table VIII)

(1) The first is what may be called the "classical" form, in this, generalised enlargement of superficial lymph-nodes, moderate in degree, is usually associated with palpable enlargement of the liver and spleen In the present series the disease assumed this form in 73 2% of the patients in 86% of these the spleen could be felt, and in about an equal proportion the liver was enlarged

TABLE VIII—PRESENTING SYNDROMES IN 212 PATIENTS WITH CHRONIC LYMPHATIC LEUKÆMIA

"Classical" type	73 2%
Splenomegalic type	11 8%
Local tumour	7 3%
Specific skin lesions	0 8%
Blood changes only	6 9%

(2) The second category is the splenomegalic type these patients often complain of abdominal pain, and physical examination reveals massive splenomegaly of the order usually associated with chronic myeloid leukæmia, there is commonly a lesser grade of hepatic enlargement, and no superficial lymph-nodes are palpable In this series 11 8% of the patients presented in this fashion

(3) The third group includes those patients who display enlargement of the lymph-nodes of one superficial group or some other solitary tumour of lymphoid tissue The onset was of this pattern in 7 3% of our patients, in the majority one superficial lymph-node was enlarged, most commonly in one of the cervical groups In 2 patients there was an abdominal tumour, shown by laparotomy to be a mass of lymph-nodes, and in a 3rd lymphoid overgrowth in the pharynx

(4) Specific skin infiltrations, although not rare, are seldom the presenting manifestation, only 2 of our patients (0 8%) coming into this group

(5) Finally, in 6 9% no physical signs of disease were evident and the characteristic changes in the blood were the only leukæmic manifestations

Diagnosis

The diagnosis of chronic lymphatic leukæmia rarely presents great difficulty, and several of the pitfalls have already been discussed

Anæmia is seldom severe when the patient is first seen, in this series, the initial hæmoglobin level lay above 70% (Haldane), or 10 4 g per 100 ml, in over half the patients, it was below 50% (Haldane), or 7 4 g per 100 ml., in about a fifth (fig 11) In 10% the initial leucocyte count was below 10,000 per c mm and in nearly half between 20,000 and 100,000 per c mm Initial counts above 500,000 per c mm were uncommon and occurred in less than 5% In 85% the small lymphocyte dominated the cytological picture, this differs from that of normal blood in its more leptochromatic nucleus, the absence of azurophil granulation, and the thin rim of cytoplasm surrounding the nucleus Cells of this kind may amount to 99% of the circulating leucocytes Less commonly the predominant cell was a medium sized lymphocyte with a circular nucleus, clearly less mature than that just described but not approaching the lymphoblast in this respect Occasionally cells with indented nuclei or other bizarre features were seen There is little correlation between the cytology and the pattern the disease may be expected to follow The medium sized lymphocyte does not necessarily portend rapid deterioration, nor the small "mature" cell an indolent course Lymphoblasts are rare and the reversion to a more primitive cellular proliferation, so characteristic of the closing stages of chronic myeloid leukæmia, is most exceptional The

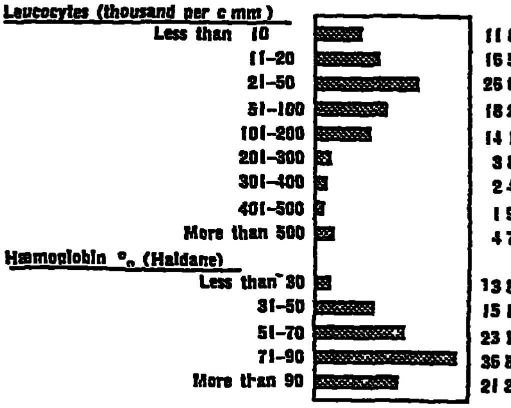

Fig 11—Initial blood-counts in 212 patients with chronic lymphatic leukæmia.

platelet count is usually normal until the stage of bone marrow failure

In almost every instance there is a constant increase in the total number of lymphocytes above 4500 per c mm , the accepted upper level of normal (Osgood et al 1939) There is, moreover, a lack of the pleomorphism which characterises reactive lymphocytosis Nevertheless diagnosis may remain uncertain when the total leucocyte count is not raised , in such circumstances a lymphoid proliferation in the bone marrow in excess of 40% of the total cell population is confirmatory (Scott 1939), although its absence does not exclude the disease In these patients biopsy of a lymph-node may provide conclusive evidence

Alterations in the serum-protein pattern have often been reported in chronic lymphatic leukæmia (Rundles et al 1954) The increase is usually in the gamma globulin fraction, but cryoglobulinæmia has been recorded (Schwartz and Jager 1949)

Less Common Clinical Features

The less common clinical features of chronic lymphatic leukæmia fall into two groups , those depending on leukæmic infiltrations in unusual sites, and those presumed to be the result of immunological disturbance

Infiltrations

Infiltrations have been recorded in every organ and tissue I shall draw attention only to the less rare, of which the present series affords examples

Cutaneous lesions have long attracted attention by their multiplicity (Gates 1938) 8 of the present series (3 8%) were affected 2 of them had generalised lymphoid erythrodermia of the *homme rouge* type , 1 had a violaceous infiltration of the cheeks , 1 had a more patchy erythrodermia , and in the remaining 4 there were blue or red nodular lesions around the orbit, on the forehead, or in the scalp

In the nervous system few abnormalities are to be recorded Facial palsy was observed in 2 patients, and paraplegia resulted from vertebral collapse in 1 Lymphomatous lesions of the conjunctiva were found in 2

Skeletal infiltrations were noted in about 5% The most common of these was an osteoporosis of the vertebral column, particularly in the lower dorsal and lumbar regions In these patients collapse of vertebral bodies was common In 1, as already noted, this accident led to compression of the cord with paraplegia , in 1 successive collapse of four vertebræ was observed The appearances are reminiscent of the diffuse decalcifying type of myelomatosis (Weissenbach and Lievre 1938) and were observed in 8 of this series This lesion may be regarded as the characteristic skeletal expression of chronic lymphatic leukæmia

In 1 case, which should perhaps be regarded as an example of plasma cell leukæmia, there were destructive lesions of most of the skeleton The peripheral leucocyte-count never exceeded 50,000 per c mm , and lymphoid cells made up 70–80% of the total From time to time a proportion of these were plasma cells, but bone-marrow puncture yielded typical lymphocytes, and the plasma-protein levels remained normal Another patient had rarefying lesions in the head of the tibia, suggesting tuberculosis

In the alimentary tract lesions were uncommon, but in 2 patients multiple lymphomatous polyps were felt in the rectum Ascites was often noted , usually an event of the final stages, at times it made its appearance early in the disease and caused great disability

Respiratory symptoms are common The frequency of infection has already been noted, and in 2 patients it led to empyema Massive mediastinal tumour is exceptional in chronic lymphatic leukæmia, although characteristic of one variety of the acute lymphoblastic type Nevertheless the mediastinal nodes naturally share in the general lymphadenopathy , sometimes they cause bronchial obstruction with subsequent infection Infiltration of the lung parenchyma is uncommon, but multiple lymphoid nodules have been recorded, often leading to obstruction and purulent bronchitis (Herold and Michel 1950) A miliary infiltration, closely resembling that of tuberculosis, was reported by Fleischmann (1909) but is of great rarity One instance was seen in the present series, in a man aged 43 The lesion appeared during the course of the leukæmia and was associated with rapidly increasing dyspnœa no evidence of tuberculosis was found and improvement was noted after irradiation

Serous pleural effusion is common and, like ascites, usually a feature of the later stages There were, however, 8 patients in this series in whom the earlier stages of the illness were associated with effusions into all three major serous cavities 6 of them were men under 50 years of age, and in all of them the disease was of the more rapidly progressive type with medium sized lymphocytes dominating the blood picture

Attention has already been drawn to the frequency of tonsillar enlargement and recurrent infection as an opening event Similar episodes are common during the course of the disease

A nephrotic syndrome was observed twice in this series No previous reports of this complication have been found

One patient was a woman of 71 years and the other a man of 57 , in both hyperglobulinæmia was noted early in the illness, but the urine was initially free from albumin Both cases were hæmatologically typical, with cells of the small mature type Œdema of the legs with purpura, but without thrombocytopenia, appeared eighteen months after the onset of the disease in the first patient, and five years after in the second At the same time heavy albuminuria, but no Bence-Jones proteinuria, was found The serum-protein levels at this stage were albumin 3 78 g per 100 ml and globulin 3 8 g in the first, and albumin 3 5 g and globulin 4 8 g in the second In both the proportion of gamma-globulin was greatly increased

Both patients sank and died of renal failure respectively six and five months after the first appearance of œdema The woman developed a nodular skin eruption which biopsy showed to be the result of amyloid infiltration, and necropsy revealed amyloid disease of her kidneys, liver, and myocardium This case recalls the amyloidosis occasionally associated with myelomatosis (Stewart and Weber 1938, Trubowitz 1950, Magnus-Levy 1952) and forms another link between this condition and chronic lymphatic leukæmia Necropsy of the other patient showed no sign of amyloidosis , there was lymphocytic infiltration in the kidneys with some hyaline change in the glomeruli In neither case did the cytology of the peripheral blood or of the bone marrow support a diagnosis of plasma cell leukæmia or of myelomatosis

Immunological Disturbances

The second group of less common clinical features are those that may be tentatively ascribed to the perverted immunity mechanisms characteristic of chronic lymphatic leukæmia These disturbances are reflected in changes in the peripheral blood The most common and the most important is auto immune hæmolytic anæmia An occult hæmolytic process has long been thought to underlie the anæmia of this disease (Brown et al 1951, Berlin et al 1954), but from time to time frank and unequivocal hæmolytic anæmia has been reported (Marchal et al 1934) It is only since the introduction of the Coombs test (Coombs et al 1945) that its frequency has been appreciated Rosenthal et al (1955) record 20 such cases

In these patients the direct Coombs test is positive and often provides a warning of impending hæmolysis , serum hæmagglutinins are often demonstrable, and indeed there is no difference between this type of auto-immune hæmolytic anæmia and the "idiopathic" variety (Dacie 1954). It has been suggested that the antibodies are derived from the pathological lymphoid tissue (Harris and Harris 1951, Wager and Chase 1952, Wiener et al. 1953). Undoubtedly this syndrome is very much more common than was believed even five years ago, and the reported incidence in this series, which is only 5·7% (12 cases), greatly underestimates its true frequency, for most of these cases have been recognised in the past five years. Hæmolysis of all grades of intensity has been encountered from that causing persistent moderate anæmia to that marked by a fall in hæmoglobin sufficiently precipitous to place the patient's life in jeopardy within a few days. A moderate rise in the serum-bilirubin level is the rule; the excretion of urobilinogen is increased; but reticulocytosis depends on the capacity of the marrow to respond to stimulation; and, as its function is usually impaired by lymphoid infiltration, figures in excess of 10% are rare. 3 of our patients died in the first hæmolytic attack; in others the process relapsed and remitted over periods lasting as long as six years. In 1 the spleen was not palpable, and, contrary to some opinion (Rosenthal et al. 1955), there was seldom any obvious parallel between its size and the severity of the hæmolytic state.

Thrombocytopenia due to similar causes undoubtedly occurs in chronic lymphatic leukæmia. In the present series there were 5 patients in whom purpura of this kind was the main cause for complaint. A low platelet count is, of course, the rule in the later stages of the disease, when it is evidence of bone-marrow failure; it is accompanied in these circumstances by anæmia, and examination of the bone-marrow reveals lymphoid infiltration with disappearance of normoblasts and megakaryocytes. In the patients in question, however, there was no anæmia and, although lymphocytes made up 60% or more of the medullary cells, megakaryocytes were present in adequate numbers. In only 1 of these patients was an agglutinin for platelets demonstrable in the serum, and in her case the Coombs test was also positive. It is difficult to avoid the conclusion that platelet auto-antibodies may be elaborated in like fashion to those active against red blood cells. A similar mechanism may be responsible for leucopenia in some cases of chronic lymphatic leukæmia, for leucocyte antibodies have been demonstrated in 1 instance (Andre et al. 1954).

The importance of appreciating this type of disturbance cannot be exaggerated, for its recognition provides an insistent call for specific treatment. Moreover the sudden appearance of anæmia or of thrombocytopenia is no longer to be regarded as the harbinger of death. 1 of our patients with hæmolytic anæmia lived six years in fair health after his first admission to hospital with a hæmoglobin level of 30%, and another lived eighteen months after a hæmolytic crisis which brought his hæmoglobin down to 18%.

Associated Diseases

It is no matter for surprise that many diseases common in the second half of life should occur in combination with chronic lymphatic leukæmia. Most of these are degenerative: ischæmic heart disease was present in 10% and essential hypertension in another 7·5%; 3 patients had diabetes mellitus, 2 gout, and 5 gall-stones; 5 had peptic ulceration and 5 prostatic enlargement. Chronic infection was rare, but 5 had pulmonary tuberculosis. Urinary calculi, which are stated to be a particularly common accompaniment (Weisberger and Persky 1953) were present in only 3.

The association with other forms of malignant disease has interested many authors (Morrison et al. 1944, Axelrod and Berman 1949, Bichel 1949). Beresford (1952) reported that 20 of 106 patients with chronic lymphatic leukæmia had other malignant lesions, although in 10 the cancer was of the skin or lip. In the present series 4·7% (10 patients) were known to have other primary tumours arising in the following sites: bronchus 3, breast 2, skin 2, and bladder, rectum, and tongue 1 each.

Treatment

The problems of treatment in chronic lymphatic leukæmia are quite different from those in the chronic myeloid variety. In myeloid leukæmia complete remission of limited duration can be confidently expected; but in lymphatic leukæmia it is unusual. Enlarged lymph-nodes may shrink, and the raised leucocyte-count may fall, but improvement in general health and repair of anæmia as a result of treatment, are rare.

The first decision the physician has to make is whether any treatment is required. In those patients in whom evidence of leukæmia is limited to lymphocytosis in the peripheral blood, therapeutic inactivity is the wise course. The same is true when there is only very slight lymphadenopathy and no significant anæmia; but when symptoms appear the patient will naturally enough demand treatment.

These symptoms may be the result of massive infiltrations in lymph nodes or other tissues, or such systemic effects of the disease as anæmia, loss of weight, and exhaustion. Undoubtedly irradiation remains the most effective means of disposing of lymphoid tumours; their radiosensitivity varies greatly, but a total fractionated dose of 1200r to any one superficial group will usually lead to satisfactory resolution of the mass. This treatment has little effect on the leucocyte-count, to lower which irradiation of the spleen is required; this measure may increase the radiosensitivity of superficial lymph-nodes and discourage recurrence in the irradiated areas (Levitt and Scott 1955).

The effect of radiotherapy on the general features of the disease is far less satisfactory. The lower the initial hæmoglobin level, the less good the outlook (Leavell 1938). In 51 patients after deep X-ray treatment the hæmoglobin level was unchanged in 32, it rose by more than 1·5 g. per 100 ml. in 7, and fell by more than 1·5 g. in 12 (Scott 1949). There are occasional exceptions in which irradiation initiates a general remission and the patient is restored for a spell to normal health. Radioactive phosphorus has little advantage over other forms of irradiation (Lawrence et al. 1949, Diamond et al. 1950).

When the symptoms are due to failure in general health without exuberant lymphadenopathy, it is rational to use one of the chemotherapeutic agents. Arsenic was much recommended in former years (Nägeli 1930) but has now been largely discarded; urethane produces temporary benefit in the occasional patient; but it is the nitrogen mustards and their derivatives which have come to occupy pride of place. Good results have been obtained with the 2-chlorethylamines (Wilkinson 1953), but sensitivity to these drugs is extremely variable in this disease. Their polyethylenimine derivatives, triethylene melamine (tretamine) (Rundles and Barton 1952, Paterson et al. 1953, Hambly and Robertson 1955), triethylene phosphoramide (Sykes et al. 1953), and triethylene thiophosphoramide (Shay et al. 1953, Leonard et al. 1956) have all been used, the first and third most extensively. Sensitivity is again variable; in most patients the leucocyte-count is reduced to normal and the lymph nodes and spleen regress, but repair of the general health is unusual. The most recently introduced and perhaps most effective drug is chlorambucil (γ-p (N,N di-(2 chloroethyl)amino phenylbutyric acid)). This is given in the daily oral dosage of 0·1–0·2 mg. per kg. body-weight for three to six weeks Toxic effects are uncommon, and reduction in leucocyte count and glandular masses is the rule, although, once again, significant gain in hæmoglobin is less frequent (Galton et al 1955, Altman et al 1956)

In the present series irradiation has been used largely for treating lymph node masses, of recent years it has been applied but rarely to the spleen Tretamine was used for two or three years with excellent effects on the white-cell counts, less on the lymph node tumours, and least on the hæmoglobin level and general health The greatest rise in hæmoglobin observed was from 7 4 g to 9 8 g per 100 ml, and this was on one solitary occasion In the last 18 patients chlorambucil has been used and the results have been similar to those obtained with tretamine, although somewhat better

In short, improvement in the hæmoglobin level, gain in weight, and recovery of general health are rarely obtained with radiotherapy or with chemotherapy It is an ironical reflection that these measures are most effective in the patients whose symptoms are so slight that the necessity for treatment is debatable

The onset of frank hæmolysis is an urgent indication for treatment with cortisone or corticotrophin Of 7 patients with auto-immune hæmolytic anæmia who were treated with steroid drugs the effect was miraculous in 5, and in the 2 others overwhelming infection was added to the hæmolytic state The remainder were observed before these drugs were available splenectomy was carried out in 1, who died with bronchopneumonia after the operation, 3 others died with uncontrolled hæmolysis, and in 1 patient blood-transfusion and splenic irradiation arrested the excessive destruction of blood on three separate occasions, before the process escaped from control to prove fatal after a course of five years

Auto immune thrombocytopenia is less easy to control, in the milder forms it improves either spontaneously or as a result of treatment with steroids Of our 5 patients 3 fell into this class, in the 2 others splenectomy was undertaken, with complete remission for seven months in one and with no effect in the other Occasional dramatic improvement results from cortisone in patients who, although anæmic, present no evidence of excessive hæmolysis, apart from a reduced survival of transfused blood

In addition to the 1 patient with hæmolytic anæmia and the 2 with thrombocytopenia, splenectomy has been carried out in 2 others in this series

In one the bulk of the organ made life intolerable, its removal three months ago has greatly increased the patient's comfort, although it is too early to judge of its effect on his disease

The other, a woman aged 45, presented with enlarged inguinal lymph nodes, biopsy of which showed the changes of lymphatic leukæmia The peripheral leucocytes numbered 17,000 per c mm, 78% of which were small lymphocytes, and 82% of the cells in films from bone marrow puncture were lymphocytes Four and a half years later there were bilateral pleural effusions and massive painful splenomegaly with a leucocyte count of only 2800 per c mm and a hæmoglobin level of 8 g per 100 ml After argument, I yielded to her entreaties to allow removal of her spleen Now, six years later, she is in abundant health, apart from an injury to her knee sustained while she was skiing last winter, there are no signs of disease, the hæmoglobin level is 16 3 g per 100 ml, the leucocytes number 4400 per c mm (lymphocytes 40%), and the bone marrow is normal

This observation confirms Galen s opinion that the spleen is an organ full of mystery, but it should not urge us to advise removal of that organ unless one of the accepted indications—uncontrollable hæmolysis, thrombocytopenia, and pain—exists (Fisher et al 1952, Reinhard and Loeb 1955)

Control of effusions into serous cavities has been very difficult In some patients wide field irradiation has been effective, and perhaps this is the most hopeful measure Injections of radioactive gold gave no benefit in 4 patients

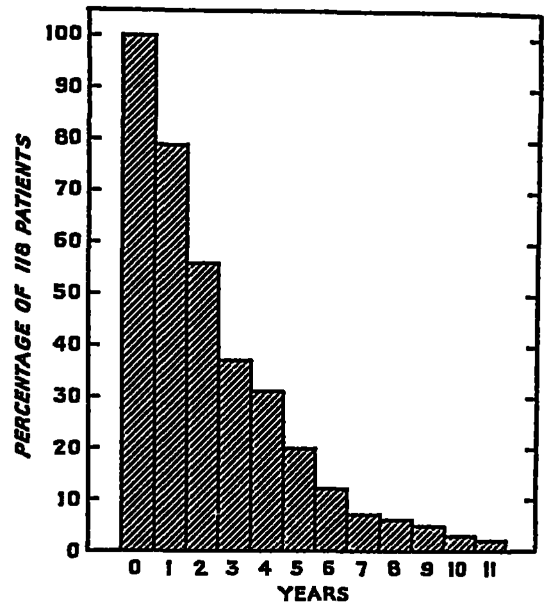

Fig 12—Survival from onset of symptoms of chronic lymphatic leukæmia

Prognosis

As one watches patients with chronic lymphatic leukæmia through their years of illness, it is possible to discern some pattern in the course of the disease Usually there is a period of reasonable health, during which the lymph-nodes and spleen increase slowly in size and the leucocyte count creeps upwards, although the hæmoglobin level and the platelet count are well maintained, then, with various degrees of abruptness, the advancing lymphoid infiltration determines bone marrow failure, the hæmoglobin level falls, a hæmorrhagic state appears, and, unless life is maintained by repeated transfusion, death follows rapidly from anæmia and exhaustion During the first phase radiotherapy or chemotherapy will lower the leucocyte count and cause the lymph nodes to regress, in the second phase treatment is seldom of avail At any time this course may be interrupted by the effects of infiltrations in such tissues as bone and skin, by infection, or by the appearance of one of the auto immune syndromes The length of the first phase varies from a few months to eight or ten years, and many of the older patients die with, rather than from, the disease (Marlow and Bartlett 1953) Rarely a patient appears to recover (Schott 1955) In this series, a woman of 80 died of bronchopneumonia ten years after the onset of chronic lymphatic leukæmia, at the time of her death there were no enlarged lymph nodes nor splenomegaly, and the blood count was normal

In the present series the mean duration of the disease in 118 patients known to have died was 36 7 months (fig 12) Survivals of 40 months in 30 untreated, and 42 months in 50 irradiated, patients (Minot and Isaacs 1924) again underline the fact that treatment has not improved the outlook in this disease

Envoi

When the third Marquess of Salisbury was Prime Minister, he is said to have dismayed his Cabinet by holding that to many important political questions there neither were nor could be answers Though it is sometimes tempting to translate this opinion to the sphere of medicine, and perhaps even to apply it to leukæmia we must remember that the science of them peutics is founded on the touchingly naïve assumption that there is an answer to every question it poses

In retrospect this review of leukæmia makes discouraging contemplation, the incidence of the disease is rising, its cause is unknown, and treatment seldom prolongs life, let alone preserves it Nevertheless those who have elected to interest themselves in the subject are inspired by the belief that answers will be found to the many problems it presents, and in the recent report from Harwell of the cure of experimental leukæmia in mice (Barnes et al 1956) the more sanguine have detected a gleam of light

POSTOPERATIVE COLLAPSE DUE TO ADRENAL INSUFFICIENCY

FOLLOWING CORTISONE THERAPY

UNIVERSITY OF BIRMINGHAM

UNTIL recently we took care not to operate on patients while they were still under corticosteroid therapy—a situation encountered particularly in cases of ulcerative colitis Cortisone was withdrawn before operation, in order to avert the postoperative complications it might cause But events have made us reverse this policy

One of us has lately recorded three cases of bowel disintegration following cortisone treatment (Brooke 1956b) In two of these the termination was the same though the patient's condition after operation was at first satisfactory, they collapsed after 18–24 hours Though their peritoneum had been much contaminated at operation, the interval before death seemed too short for infection to be the main cause of the collapse Moreover, soon afterwards a similar death followed an operation at which contamination was only slight

Case 1 —A woman aged 52, with ulcerative colitis, had received cortisone 50 mg t.d s for 2 weeks On her admission to hospital, cortisone was stopped, and aqueous intramuscular corticotrophin (A C T H) 20 units was given daily for 2 weeks This was withdrawn a few days before operation Her general condition was good and primary panproctocolectomy was performed, the operation was straightforward, though there was slight contamination The blood-pressure (B.P) remained normal until 7 hours later, when it suddenly fell Response to methedrine and noradrenaline was transient, and she died 13 hours after operation

In none of these patients did necropsy show any cause for the sudden collapse It seemed possible, however, that adrenal insufficiency might be responsible, though in case 1 the adrenals appeared normal both to the naked eye and after examination by conventional histological procedures, with a combined weight of 16 g (rather higher than normal, possibly because of the effects of corticotrophin) The right suprarenal of one of the patients previously reported (case 2, Brooke 1956b) had been found to be necrotic following thrombosis of its vein Salassa et al (1953) had reported deaths from adrenal insufficiency in patients with adrenal cortical atrophy following protracted cortisone therapy the adrenal cortex showed no obvious atrophy but definite histological changes Similar reports have come from Fraser et al (1952) and Lewis et al (1953), and Harnagel and Kramer (1955) recorded successful treatment with cortisone in a case of postoperative collapse following manipulation of the knee joint which required but 5 minutes' anæsthesia

Adrenal insufficiency therefore seemed a likely cause of death in our cases Administration of cortisone is known to produce adrenocortical hypoplasia and even frank atrophy through suppression of endogenous corticotrophin This cortisone induced depression takes several days to pass off, and even after the response to corticotrophin has been fully restored, it may be a very long time before the hypoplastic gland returns to absolute normality During this period, though the adrenal glands are capable of producing enough steroids for ordinary daily requirements, they may be unable to meet the additional requirements of severe stress During this period, which may last as long as 6 months to 2 years (Hench and Ward 1954), a major operation could have disastrous results With these facts in mind, we decided that in

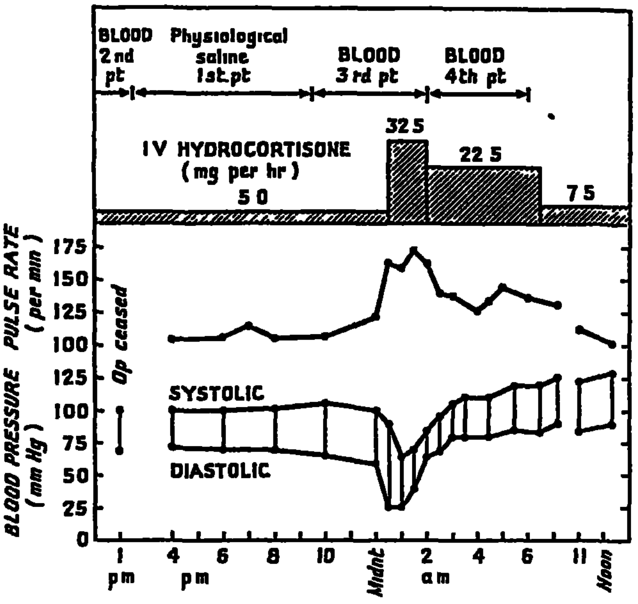

Fig 1—Case 2

operating on patients who have had a course of cortisone we would henceforth give corticosteroids over the operative period

Case 2—A woman aged 29, developed severe ulcerative colitis during the puerperium following the birth of her second child She did not respond to a course of cortisone (100–150 mg daily) lasting 6 weeks Therapy ceased 10 days before operation, but was recommenced 3 days before primary colectomy, with corticotrophin 20 units b d s, followed next day by prednisone 5 mg q d s, at operation, therapy was maintained with intravenous hydrocortisone 50 mg per pint of physiological saline solution Operation was uneventful Her condition and blood pressure (100/65) remained satisfactory until 12 hours later, at 12 30 A M, when she collapsed with a blood pressure of 75/30 She was then given hydrocortisone 50 mg intravenously followed, at 2 0 A M, by 100 mg No vasopressor drugs were administered, her condition improved with a gradual return of blood pressure to normal by 6 0 A M Convalescence remained smooth from 6 0 A M on the first postoperative day (fig 1)

This patient had collapse and hypotension, with no obvious cause, in a manner and at a time identical with those in our previous cases She was revived by cortisone treatment alone

Case 3—A woman, aged 43, was admitted as an emergency with perforation of the colon following 6 weeks of cortisone treatment Emergency ileostomy was followed by persistent hypotension (B P 94/70 mm Hg) This was unrelieved by the usual measures, but cortisone 100 mg initially, given intramuscularly, followed by 50 mg daily for 3 days with corticotrophin 10 units b d, restored and maintained her condition 11 days later colectomy was undertaken with a repetition of postoperative hypotension which was corrected only by a similar regime using hydrocortisone and corticotrophin While she was receiving these drugs, her abdomen burst on the 8th day after colectomy, it finally proved impossible to raise her blood pressure, which fell after resuture, and she died

Hayes and Kushlan (1956) report intractable shock in five of twelve patients previously treated for ulcerative colitis with corticosteroids In four, collapse attended operation, in the fifth it began with the induction of anæsthesia Treatment of shock with corticoids was successful, and the condition was avoided at subsequent operations by their administration before, during, and after operation But this state is not confined to ulcerative colitis in fifteen of twenty eight patients who received steroids at some time (for either ulcerative colitis splenic disease, or rheumatoid arthritis) shock refractory *to blood-transfusion followed an operation, whereas the* condition of twenty five who had similar diseases, but who had not received corticoids, remained satisfactory after undergoing operations (Hayes 1956) This has also been our experience

Case 4—A woman, aged 51, had received cortisone 100 mg daily for 5 weeks for acquired hæmolytic disease Treatment ceased at the time of splenectomy, she collapsed 24 hours later (B P 90/50) and responded to 50 mg cortisone intramuscularly followed by 25 mg, the blood pressure rising to 115/80

In our series seven patients have had shock due to adrenal insufficiency (table I), all three who received no planned course of corticoids to counter this died, whereas all but one of the remainder survived Since we have given corticosteroid cover immediately before during, and after operation, this form of postoperative shock has been conspicuous by its absence in eight patients severely ill with ulcerative colitis after previous corticoid therapy 10 operations were performed with uninterrupted recoveries following primary colectomy (5), primary panproctocolectomy (2), or excision of the rectum (3) One of the patients undergoing primary colectomy is of particular interest because though his blood pressure did not fall after this major operation, it fell after a minor operation undertaken subsequently when cortisone cover had been withdrawn

Case 5—A man, aged 41, was *admitted for surgery* 2 months after a course of cortisone followed by prednisone lasting a month Primary colectomy was performed under cortisone cover (table II) without incident, his blood pressure remaining steady throughout convalescence 17 days later just after corticosteroids had been withdrawn, a small skin

TABLE I—POSTOPERATIVE COLLAPSE IN PATIENTS RECEIVING CORTISONE THERAPY BEFORE OPERATION

Sex and age		Diagnosis	Duration of corticoid treatment	Cortisone preoperative total dose	Operative cover	Corticoids for post operative shock	Outcome
F	41	Ulcerative colitis	1 2–3 weeks	Not known	No	No	Died
M	[illegible]	Ulcerative colitis	Cortisone 4 weeks corticotrophin 40 u daily 5 days preop	5 25 g	No*	No*	Died
F	[illegible]	Ulcerative colitis	Cortisone not known, corticotrophin 20 u daily 14 days preop	Not known	No	No	Died
F	43	Ulcerative colitis	Cortisone 6 weeks	3 g	No	Yes	Initial recovery Survived colectomy 10 days later with cortisone and corticotrophin Died 9 days later following further operation for burst abdomen
M	[illegible]	Ulcerative colitis	Cortisone 4 weeks corticotrophin 40 u daily 4 days preop	9 g	No	Yes	Recovery despite subsequent rectal hæmorrhage and burst abdomen
F	51	Acquired hæmolytic anæmia	Cortisone 6 weeks	4 75 g	No	Yes	Recovery
F	29	Ulcerative colitis	Cortisone 6 weeks corticotrophin 40 u. daily 7 days preop	5 g	Yes	Yes	Uneventful recovery

* This patient received 100 mg cortisone during operation empirically, but at no time received steroids as planned cover or to counter final collapse

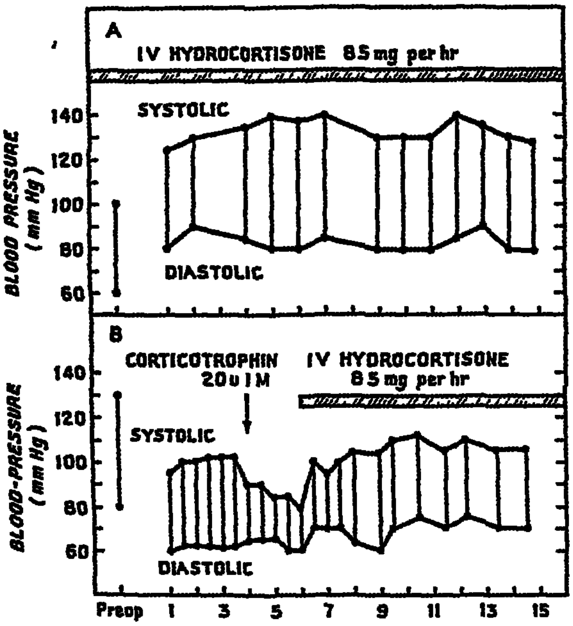

Fig 2—Case 5 A, primary colectomy and cortisone cover B, skin-graft to anal ulcer no cover

graft was applied under general anæsthesia to an ulcer in the anal area This was a minor procedure causing little or no bleeding, no further cortisone cover was given His blood-pressure following operation fell to 100/60, from a preoperative level of 130/80 4 hours later it had fallen to 90/65, and 2 hours after this to 80/60 At this point it was deemed advisable to institute steroid therapy, corticotrophin 20 u was given intramuscularly, and hydrocortisone intravenously by continuous drip, 100 mg in 12 hours Within 5 hours the blood pressure had stabilised at 110/70, and the patient's general condition was excellent The cortisone was gradually withdrawn over the ensuing days under corticotrophin cover with no further fall in blood pressure (fig 2) Subsequent excision of the rectum under corticosteroid cover was without incident

Hypotension without collapse has also been seen

Case 6 —A woman, aged 33, had had a course of cortisone during the 2 months before admission for surgery Primary colectomy was done 2 months after the end of the course, and though convalescence was uneventful, her blood-pressure (106/66 before operation) remained at about 100/70 for 24 hours, the possible reason for this was not appreciated at that time 6 months later she returned for excision of the rectum, her blood-pressure was then 140/80 Following operation, which was performed without difficulty and with little blood loss, pressure recordings on each successive day were 85/50, 95/60, 100/70, 90/45, 95/65 95/65, 96/50, and 100/65 They remained at 100/60 for a fortnight after operation Nevertheless, her condition gave no cause for concern, for she was never shocked She was found to be excreting only 1 mg of 17-ketosteroids in 24 hours which suggested adrenal atrophy, corticoids were, however, withheld, because a tuberculous pulmonary focus had developed between the two periods of admission

TABLE II—SCHEME OF CORTISONE AND CORTICOTROPHIN DOSAGE DURING OPERATIVE PERIOD

Day	Cortisone (hydrocortisone where stated)	Corticotrophin
O − 2	Nil	20 u i m i b d
O − 1	50 mg i m i 6 P M	20 u i m i b d
O	50 mg oral 6 A M 50 mg i m i with premedication Postoperatively hydrocortisone 100 mg i v by continuous drip in 12 hours	20 u i m i b d
O + 1	Hydrocortisone 150 mg i v by drip in 24 hours	20 u i m i b d
O + 2	50 mg i v by drip 12 noon, 25 mg 10 P M 25 mg	20 u i m i b d
O + 3	25 mg t d s	20 u i m i b d
O + 4	25 mg b d	20 u i m i b d
O + 5	25 mg	20 u i m i b d
O + 6	Nil	20 u –10 u i m i
O + 7	Nil	10 u b d
O + 8	Nil	10 u
O + 9	Nil	Nil

O operation i m i intramuscular injection i v, intravenously
All postoperative cortisone is given by mouth unless patient has ileus, &c Corticotrophin is given in an aqueous solution

The suggested dosage for prophylactic treatment is set out in table II The scheme is based on the fact that cortisone administered orally is most effective 4–8 hours later, intramuscularly, 8–12 hours later, and intravenously (as hydrocortisone), almost immediately but only for a short time Given intramuscularly, corticotrophin acts optimally 6–8 hours afterwards, but intravenously its effect is rapid and long-continued (Hench and Ward 1954) Especial vigilance is needed because patients treated thus are prone to gastric and duodenal ulceration, and to infection

Discussion

In ulcerative colitis, more than any other condition, surgical intervention is likely to follow a course of corticosteroids Postoperative shock due to adrenal insufficiency will therefore be seen mostly in patients with this disease In the Medical Research Council's trial of cortisone for ulcerative colitis forty-five patients (a fifth of the original group) ultimately required surgery (Truelove and Witts 1955) and fourteen died, giving a mortality of 32% as opposed to the overall mortality for surgery (Swinton 1956, Brooke 1956a) of 10–12% in the pre cortisone era Patients who do not respond to cortisone often deteriorate during its administration, and this must partly account for the higher operative mortality in the cortisone trial Truelove and Witts observed that most deaths took place soon after the initial operation, adrenal insufficiency may therefore have played a part in the high death-rate According to Salassa et al (1953), 5 days' administration of cortisone is enough to cause histological changes in the adrenal cortex Hench and Ward (1954) say that a total dose of 2 g is likely to induce frank atrophy, the M R C trial, when followed to the limit of 6 weeks, provided twice that critical dose In five of the seven patients of our series who had postoperative adrenal shock the dosage is known; all had previously received over 2 g cortisone (table I)

Before cortisone is given for any condition, the likelihood of surgery being required later must be considered, together with the increased risk if it is undertaken after cortisone By no means all patients who have received cortisone go into shock after operation, some have hypotension without shock (case 5), others show no ill effects Though tests have been devised for adrenal insufficiency (Hench and Ward 1954) it is difficult to predict which patients will become shocked, and therefore wise to perform any subsequent operation under the cover of corticosteroids

Salassa et al (1953) have said that adrenal insufficiency may persist up to 2 years after cessation of cortisone, in our case 6 it was still present after 8 months Post operative collapse may take place even in a patient under routine cortisone cover (case 2), in these circumstances more cortisone should be given intravenously in the form of hydrocortisone, for intramuscular injections are absorbed too slowly Signs of hypercorticism during the initial course of cortisone are an absolute indication for the provision of cortisone cover at a subsequent operation, since atrophic changes within the adrenal are to be expected in these cases (Hench and Ward 1954) When considering the advisability of treating a patient with cortisone, a factor to be weighed is the need to give cortisone again later if surgery should be required The risks of such cortisone cover for operations—i e, ulceration in the upper alimentary tract, greater likelihood of infection, and (in particular) septicæmia—will be by no means negligible

Summary

Patients who have received cortisone are liable to collapse when later submitted to the stress of operation subsequently There is evidence that this state of shock is the outcome of adrenal insufficiency due to atrophic changes within the adrenal cortex induced by cortico steroid therapy Death in three patients could be explained only on these grounds Shock was successfully treated in four other patients by the further administration of cortisone, though one eventually died

It is suggested that cortisone should be administered prophylactically to any patient undergoing operation who has had corticosteroid therapy within a year, and possibly two years, of the operation, cortisone cover should include the operation-period and be withdrawn during convalescence A scheme of dosage is proposed Since this scheme was followed, eight such patients have been treated without collapse in any

The complications usually associated with cortisone therapy must be expected while prophylactic cover is being maintained—especially a tendency to infection and septicæmia Such infections require larger doses of antibiotics than usual for their control

In any patient for whom corticosteroid therapy is contemplated, careful consideration should be given to the likelihood of operation being needed Operative risks are increased by antecedent administration of cortisone

We wish to acknowledge the assistance given by Dr W T Cooke in the preparation of this paper and for permission to record cases under our joint care We wish to thank Mr J C Edwards for permission to report case 3 and Dr E Bulmer for case 4

RADIOLOGIST, CENTRAL MIDDLESEX HOSPITAL, LONDON

Large series of cases of Paget's disease of bone (diagnosed radiologically) have been reported by Dickson, Camp, and Ghormley (1945), Brailsford (1938), and others, but there has been no report of the radiological incidence of the disease at differing ages Necropsy studies by Schmorl (1932) and Collins (1956) on unselected subjects over 40 years of age have shown an incidence of 3% and 3 7% respectively

In the ten year period 1947–56, 689 cases of Paget's disease have been diagnosed in the radiological department of the Central Middlesex Hospital Table I shows their age and sex distribution

TABLE I—AGE AND SEX DISTRIBUTION IN 689 CASES DIAGNOSED AS PAGET'S DISEASE

Age group	Men	Women	Total
25–24	1		1
35–44	11	7	18
45–54	27	13	40
55–64	111	57	168
65–74	192	86	278
75–84	104	45	149
85 +	17	18	35
Total	463	226	689

For the six year period 1947–52 it was possible to divide the 357 cases of Paget's disease discovered (245 men and 112 women) into two groups according to whether the diagnosis was made initially as a result of an examination which included the lumbar spine and pelvis, or as a result of examination of any other site There were 289 patients in the first group (204 men and 85 women) and 68 patients in the second group (41 men and 27 women) It is well recognised that, radiologically, the pelvis is the most fruitful area of examination for Paget's disease thus in the series of Dickson et al (1945) the pelvis was involved in 243 out of 367 cases and in that of Rosenkrantz et al (1952) it was involved in 60 out of 111

As a sample of the 69,783 patients radiographed during this six-year period 3000 X ray record cards were examined to see what proportion of patients of different sexes and ages had an examination involving the lumbar spine and pelvis area—including, for example, an examination of the urinary tract or a barium enema From the information thus obtained, it was possible to estimate the total number of patients in whom this area was examined

Table II sets out the age and sex distribution of the 289 patients in whom the diagnosis was made from examination of the pelvis and lumbar spine and in parentheses the estimated number of persons similarly examined in the same age group

TABLE II—CASES OF PAGET'S DISEASE OF BONE

Age group	Men	Women	Total
35–44	6 *(1466)*	4 *(1466)*	10 *(2932)*
45–54	7 *(1956)*	7 *(1466)*	14 *(3422)*
55–64	48 *(1675)*	16 *(1187)*	64 *(2562)*
65–74	88 *(1157)*	38 *(1047)*	126 *(2234)*
75–84	49 *(698)*	12 *(419)*	61 *(1117)*
85 +	6 *(70)*	8 *(70)*	14 *(140)*
Total	204 *(7052)*	85 *(5655)*	289 *(12 707)*

From table II the rate per 1000 persons at different age groups was calculated (table III) Only the last group, the 85+, is too small for any reliable information to be obtained from it

From table III it appears that the incidence in men alters little from 35 to 54 years but after 55 it increases rapidly to a steady high level which is reached in the decade 65–74, after 75 it shows little change In women the incidence under 55 years is surprisingly similar to that of men of the same age, but after 55 the increase is only to a rate about half that of men of the same age, except possibly in the 85+ group where the rate rises sharply to the male level

Taking the average of both sexes combined over the age of 45 years (279 patients with Paget's disease among 9775 examined) the incidence of 3 5% is surprisingly near that of Collins for subjects over 40 years of age

It is of interest that in the larger series of 689 cases of Paget's disease only 3 sarcomas were encountered—one in a man of 78 with extensive Paget's disease in the pelvis and both femora who had developed an osteolytic lesion of his

TABLE III—PAGET'S DISEASE OF BONE (RATE PER 1000)

Age group	Men	Women	Average both sexes
35–44	4 0	2 7	3 4
45–54	3 6	4 8	4 0
55–64	29 0	13 5	22 4
65–74	73 9	36 2	56 5
75–84	70 2	28 6	51 3
85 –	85 7	114 3	90 6
Average	28 9	15 0	22 8

right femur, another in a man of 56 with an osteolytic lesion in the right ilium who had Paget's disease limited to the pelvis, and the third in a woman of 58 who had an osteochondro-sarcoma of the sacrum as well as Paget's disease of the pelvis.

Summary

A consecutive series of 689 patients with Paget's disease is reported. In part of the series it was possible to correlate the number of radiographic examinations which included the lumbar spine and pelvis with the number of cases of Paget's disease so encountered.

The incidence of Paget's disease in both sexes was nearly equal below the age of 54 years but thereafter the male rate rose rapidly to a high level in the period 65–74 when it was approximately double the female rate.

Above the age of 75 the male rate showed little alteration. In women the rate appeared to rise sharply to the male level over the age of 85.

Sarcoma was encountered only 3 times in the series.

SEASONAL INCIDENCE OF MEGALOBLASTIC ANÆMIA OF PREGNANCY AND THE PUERPERIUM

R. B. THOMPSON
M.D. Durh., M.R.C.P.
LECTURER IN MEDICINE, KING'S COLLEGE, UNIVERSITY OF DURHAM, AND ASSISTANT PHYSICIAN, PRINCESS MARY MATERNITY HOSPITAL, NEWCASTLE UPON TYNE

MEGALOBLASTIC anæmia of pregnancy in the tropics is generally considered to be due to nutritional deficiency; patients often respond to vitamin-B_{12} therapy, although folic acid and other deficiencies are often present as well. The rôle of dietary deficiency in the ætiology of megaloblastic anæmia of pregnancy in temperate climates is, however, by no means so certain. If dietary deficiency is a significant factor, more patients might be expected to develop the disorder during the winter and spring than during the summer and autumn (see below). The present study was made to find if any such seasonal variation existed.

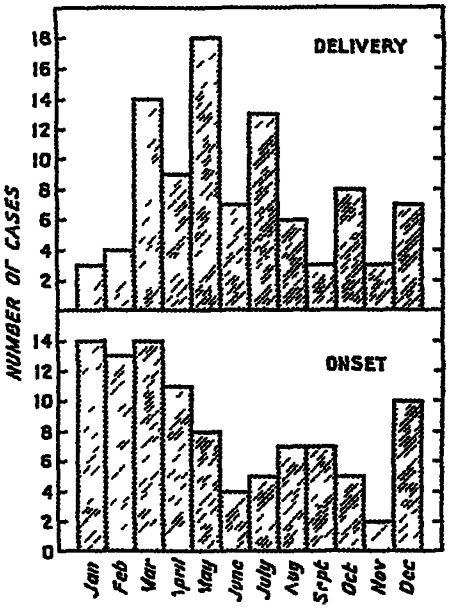
Methods

The hæmatological methods were essentially the same as those described by Thompson and Ungley (1951). In all the present cases megaloblastic erythropoiesis was found either by marrow biopsy, blood film, or buffy-coat smear (Goodall 1955). All the recent cases responded satisfactorily to folic acid; the treatments used in the earlier cases have previously been described (Thompson and Ungley 1951).

The date of delivery was always readily obtained. The date of onset of anæmia could not be determined with any accuracy in most of the patients; it could, however, usually be assessed to within about a month. Errors of a month, or even of two months, would not effect the main conclusions, for the onset of symptoms was always either about the time of delivery or, more commonly, about the 7th–8th month of pregnancy. Since full blood examinations have been made for some years on all patients attending the antenatal clinic in whom the Hb was less than 70%, the date of onset of anæmia could often be ascertained to within a month. Unfortunately, many patients were admitted late in pregnancy or in the puerperium, and the date of onset had to be assessed from the patient's symptoms and from data supplied by the family doctor. Soreness or ulceration of the tongue was a useful guide, especially when taken with the onset of symptoms such as general tiredness, loss of appetite, vomiting, pallor, and breathlessness.

Material

The case-records of 105 patients were available for this study: 36 from a general hospital, to which most of them were admitted in the puerperium, 55 from one maternity hospital, and 14 from another. In neither of the maternity hospitals was there any seasonal variation in the number of deliveries.



Monthly incidence of onset of megaloblastic anæmia and of parturition.

The 1st patient of the series was seen in 1933 and all available cases were included up to October, 1956. In recent years, since the clinical and hæmatological picture has become better recognised, most patients have been diagnosed during pregnancy, whereas most of the earlier cases were puerperal.

In 5 patients the dates of delivery are known, and these are included in parentheses in the accompanying table; it was, however, impossible to assess the date of onset of symptoms in these patients, and they have not been included in the main analysis or in the accompanying figure.

Results

The results are presented in the figure and the table, which show that there were significantly more deliveries in the six-month period from February to July inclusive than during the other half of the year. Since the onset of the disorder is commonly about two months before delivery, the table and the figure show a similar seasonal incidence but in an earlier six-month period. Thus the onset was in the period December–May in 70 patients and the period June–November in 30.

Discussion

The results are most readily explained by postulating that dietary deficiency during the winter months plays a significant part in the ætiology of megaloblastic anæmia of pregnancy. That such a factor is important in scurvy has been long recognised; indeed it was the possible analogy with scurvy that suggested the present study.

The richest animal source of folic acid is liver, the total folic acid content of 100 g. of beef liver being stated by

MONTHLY INCIDENCE OF ONSET OF MEGALOBLASTIC ANÆMIA AND OF PARTURITION

Month	Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec	Total
Delivered	3 (1)	4	14 (2)	12	18	7	13	6 (1)	4 (1)	8	4	7	100 (5)
Onset	14	13	14	11	8	4	5	7	7	5	2	10	100

[1] The figures in parentheses refer to 5 patients in whom the date of onset of anæmia could not be assessed.

the U S Human Nutrition and Home Economics Bureau (1951) to be nearly 300 µg

Fresh green vegetables are the most important vegetable source, the richest content being usually associated with the greenest leaves (Olson et al 1947)

Spinach, for instance, has a total folic acid content of 49–115 µg and a free folic acid content of 31–110 µg per 100 g when fresh

The total and free folic acid contents respectively of broccoli, brussels sprouts, and cauliflower are 33 9 and 8–14, 27 1 and 11 7, 29 1 and 8 5 µg per 100 g

Some beans—e g, dry Lima beans—contain 103 and 16 36 µg total and free folic acid respectively per 100 g Root vegetables are usually unimportant sources, and most fruit contains but little folic acid Some nuts and some breakfast cereals prepared from wheat—e g, wheat bran and shredded wheat—are quite good sources These values just cited are mainly derived from the U S Human Nutrition and Home Economics Bureau (1951)

The folic acid content of green vegetables and of meat (but to a much lesser extent that of liver) is mostly destroyed by cooking and canning (Cheldelin et al 1943, Hanning and Mitts 1949) Spinach is unusual in that it retains much of its folic-acid activity after canning, most vegetables retain their activity well on storage in refrigerators (Fager et al 1949) If liver is not frequently eaten, it is clear that much of the supply of folic acid must come from fresh green vegetables, which are unavailable in winter It may well be that in winter other dietary sources are inadequate to meet the increased needs for folic acid during pregnancy, and that deficiency results The vomiting, of which patients with megaloblastic anæmia of pregnancy so often complain, will decrease yet further the folic-acid intake

Day et al (1949) reported that, in megaloblastic anæmia of pregnancy, the urinary excretion of hormones was abnormal That these patients might produce an abnormal steroid which antagonises folic acid was suggested by Thompson and Ungley (1951) and Girdwood (1953, 1954) It is my impression that hæmatopoietic responses are poorer during pregnancy than in the puerperium, if this is confirmed it might support the hormonal idea, but it is difficult to explain on such a hypothesis the cases seen several months after delivery The hormonal theory could also explain the high incidence of twin pregnancies in the series There were ten sets of twins in the 100 cases, the expected incidence being about 1 in 80 births Increased demands for folic acid would also be expected, however, in twin pregnancy Again, a seasonal variation would hardly be expected if this hormonal antagonist theory were true No evidence has been produced to suggest that malabsorption plays a part in the ætiology of the deficiency (Badenoch et al 1955 Girdwood 1956)

The reason why patients with the disorder in temperate climates develop a predominantly, if not exclusively, folic acid deficiency is explained by Vinke and Van der Sar (1956), who point out that healthy people have a store of vitamin B_{12} which can supply their requirements for many months and sometimes for years The store of folic acid on the other hand, can supply the needs of the body for only about a month In a previously well-nourished person with increased demands for both substances and with a poor dietary intake folic acid deficiency becomes manifest much earlier than does a deficiency of vitamin B_{12} In a previously malnourished person with a low store of vitamin B_{12}, however, the deficiency is likely to be of both vitamin B_{12} and folic acid, this would obtain in patients developing megaloblastic anæmia in the tropics

The evidence presented here does not warrant the assumption that all cases of megaloblastic anæmia of pregnancy are due to dietary deficiency but it suggests that dietary deficiency is at least an important contributory cause It is interesting that the disorder disappeared from the wards of a maternity hospital in Montreal when an antepartum daily supplement of 4 5 µg of vitamin B_{12} and 3 0 mg of folic acid was given (Lowenstein et al 1955)

Summary

A study of 100 cases of megaloblastic anæmia of pregnancy has shown an increased incidence of the disorder during the winter and spring months This suggests that dietary deficiency is at least a contributory cause of the disorder

My thanks are due especially to Dr C C Ungley for allowing access to his case notes and to Prof H Harvey Evers, Mr W Hunter, Mr Linton Snaith, and Mr Frank Stabler for allowing me to study patients admitted under their care

STAPHYLOCOCCUS AUREUS IN THE FÆCES OF HOSPITAL PATIENTS

J Q Matthias
M B Lond, M R C P, F F A R C S

R A Shooter
M A, M D Camb

R E O Williams
M D Lond

From the Department of Bacteriology, St Bartholomew's Hospital, London, and the Staphylococcus Reference Laboratory, Public Health Laboratory Service, Colindale, London

Patients with *Staphylococcus aureus* in their stools may be a source of ward cross infection (Brodie, Kerr, and Sommerville 1956) We describe here an investigation made to determine the frequency of fæcal carriers at St Bartholomew's Hospital, and we draw attention to a method of diagnosing acute staphylococcal enterocolitis

Methods

Nasal swabs and stools were obtained from patients in a medical and surgical unit (each having male and female wards) as soon as possible after admission and afterwards weekly when possible The nasal specimens were cultured on blood agar and incubated at 37°C overnight, the stool specimens were cultured on nutrient agar containing 7% sodium chloride and incubated at 37°C for forty eight hours Representative colonies resembling *Staph aureus* were tested for coagulase production, and single colonies of all coagulase positive strains were typed by the phage method The number of colonies of *Staph aureus* on the positive plates ranged between 1 and 40

Results

Of 196 patients, 194 had nasal swabs examined within three days of admission and 76 of these (39%) yielded *Staph aureus*, 142 had stools examined within seven days of admission with 32 (23%) positive

153 patients had more than one nasal swab tested 30% yielded *Staph aureus* on each occasion, 41% were

negative each time, and 29% had at least one specimen positive and one negative For the 112 patients with two or more stool specimens tested, the corresponding figures were 11%, 60%, and 29% respectively

Stool carriers had staphylococci in their noses significantly more often than non-carriers (see table) 79% of 62 patients with at least one stool positive had a positive nasal swab, compared with 45% of 109 patients who never yielded staphylococci in their stools 21 patients yielded staphylococci from their stools on more than one occasion, 16 of these (76%) were also persistent nasal carriers

ISOLATION OF *Staph aureus* FROM NOSES AND STOOLS OF INPATIENTS

—	Noses		
	+	−	Total
Stools +	49	13	62
Stools −	49	60	109
Not tested	9	16	25
Total	107	89	196

+ at least one positive specimen −, no positive specimen

There was an indication that the frequency of stool carriage increased with the time the patient had been in hospital

From 35 patients, staphylococci from both nose and stool were typed by the phage method 22 yielded strains of the same phage type in nose and stool on at least one occasion A further 5 had untypable strains in both sites 7 had two different staphylococci in the nose, and 1 had three Of 16 patients with strains of phage group I in the nose, 7 yielded the same type from the stools, with group II the corresponding figures were 6 and 4, and with group III 13 and 9

No relation was detected between nose or stool carriage and antibiotic treatment, nor were there detectable differences between men and women or between surgical and medical patients

Discussion

Our results confirm the findings of Brodie et al (1956) on the frequency of *Staph aureus* in the stools As with nasal carriage so with fæcal carriage some people seem to carry persistently, some intermittently, and some rarely in the fæces

Apart from the potential reservoir for ward infection, which is difficult to assess because so many of the stool carriers are also nasal carriers, this finding is important in relation to the diagnosis of staphylococcal enterocolitis Whether the patient's own staphylococci can cause this disease or whether the disease always results from cross-infection with another strain is not known, but in either case the fact that staphylococci are not uncommonly present in the stools of healthy people means that, by itself, a stool culture may be misleading in the diagnosis of enterocolitis—besides taking too long to be useful in the more acute cases We have seen about 30 patients thought to have staphylococcal enterocolitis, 1 died three days after an operation for partial gastrectomy, and the others survived with treatment or had relatively mild infections The initial laboratory diagnosis was made on the presence of clumps of Gram positive cocci in stained films of the stools, an appearance seen only once in a large number of stools from patients without staphylococcal enterocolitis More experience is needed to judge the full reliability of this examination, but for the present it seems to us that this simple and rapid test ought to be done as a routine for patients with diarrhœa after treatment with broad spectrum antibiotics

Our thanks are due to Mr M P Curwen, M.A, for help in analysing the figures, to the nursing staff of the medical and surgical professorial units for their help in collecting the specimens, and to Dr M P Jevons and Miss Joan Rippon, PH D, for the phage typing of the staphylococci

AN IMPROVED METHOD FOR EXTRACTING OXYTOCIC AND ANTIDIURETIC HORMONES FROM BLOOD

G W Bisset
M B Lond, D Phil Oxfd
ASSISTANT LECTURER IN PHARMACOLOGY

J Lee
M B Lond, M R C P
CHIEF ASSISTANT, ENDOCRINE UNIT, PART-TIME SENIOR LECTURER IN PHYSIOLOGY

CHARING CROSS HOSPITAL AND MEDICAL SCHOOL, LONDON

In a previous paper (Bisset, Lee, and Bromwich 1956) a method was described for extracting the hormones of the neurohypophysis from human blood When pituitary (posterior lobe) extract (P P L E) was added to blood and extracted, approximately one third was recovered A considerable part of the activity was lost in evaporating the extracts to dryness at 40°C Subsequent work has shown that this loss can be avoided by concentrating in a vacuum desiccator It has been found also that if the blood samples are centrifuged immediately after the addition of acid alcohol, and not left to stand for three or four hours, as originally described by Melville (1937), at least three quarters of the activity can be recovered in the supernatant

The method of extraction has now been improved by the inclusion of these two modifications P P L E, vasopressin, and oxytocin have been added to blood and extracted in order to estimate the recovery of activity obtainable with the new method

Methods

Collection of Blood Samples—Blood was obtained from the median cubital veins of human subjects, from the carotid arteries of rats under ether or ethanol anæsthesia, and from the femoral artery of a dog under pentobarbitone sodium

For the collection of human blood a *siliconed* glass syringe (Bisset and Lee 1956) was used, containing a trace of heparin solution (25,000 u per ml), and for blood from the rat or dog, a *nylon* syringe containing 50 u heparin in 1 0 ml of 0 9% saline

To 5 0 ml samples of blood was added either P P L E (' Pituitrin ') 100 mu, oxytocin (' Pitocin ') 100 mu, or vasopressin (' Pitressin ') 10 mu (preparations of Parke, Davis & Co)

Preparation of Extracts—The following is a description of the modified method which was used to prepare the extracts

(1) The blood was added to 9 vols of 80% (*v/v*) ethanol in a 'Polythene' beaker, and normal sulphuric acid added until the mixture was blue to Congo red

(2) The mixture was shaken vigorously and centrifuged at once

(3) The supernatant from (2) was concentrated by distillation in vacuo at a temperature not exceeding 50°C, until reduced to a volume of 10 ml or less The residue was centrifuged

(4) The supernatant from (3) was placed overnight in a vacuum desiccator containing enough phosphorous pentoxide to ensure concentration to about 2–3 ml Evaporation to dryness under these conditions is permissible

(5) The residue from (4) was taken up in distilled water and the solution dialysed in a ' Cellophane ' membrane (' Nojax '

RECOVERY OF ACTIVITY OF PITUITARY HORMONES ADDED TO BLOOD

Experiment no	Source of blood	Percentage recovery of activity	
		Oxytocic	Antidiuretic

casings 8/32) against running tap-water for forty five minutes The final extract was not neutralised until needed for assay

Assay of Extracts —Methods of assay were as previously described (Bisset et al 1956)

Results

The table shows the percentage recovery of activity of pituitary (posterior lobe) hormones added to blood In experiments 1–9, P P L E was added, in experiments 10, 11, 12, and 14, oxytocin, and in experiment 13, vasopressin The mean recoveries of oxytocic and antidiuretic activity from rat blood (experiments 1–5) were 73% and 75% respectively The corresponding figures for human blood (experiments 6–13) were 79% and 60% The recovery of oxytocic activity from dog blood was 79% The mean recovery of oxytocic activity for the whole series of experiments was 77% (S E ±5 01) and of antidiuretic activity, 68% (S E ±5 38) There is no significant difference between these means ($P > 0\ 1$) Under the conditions in which the experiments were carried out endogenous oxytocic and antidiuretic activity was negligible

In every experiment oxytocic activity was abolished by treatment of the extracts with 0 01 M sodium thioglycollate (van Dyke et al 1942) It was not thought necessary to apply this test routinely to antidiuretic activity, for assay by intravenous injection in the rat is almost specific for antidiuretic hormone (A D H)

Discussion

The introduction of two modifications in a method for extracting oxytocin and antidiuretic hormone from blood has resulted in an increase in recovery from about one-third to more than two thirds Experiment has shown that there is an initial loss of at least 10% of the activity during centrifugation of a blood sample, for only 90% of the total amount of fluid present in the sample is recovered in the supernatant Therefore any further loss of activity during concentration and dialysis of the extract does not exceed a mean of 20% Immediate centrifugation of the blood samples considerably shortens the time required for the preparation of extracts The hormones are stable in the supernatant which may conveniently be left overnight in the refrigerator and concentrated on the following day

The fact that there is no significant difference between the mean recoveries of oxytocic and antidiuretic activity from blood suggests that no extraneous factors are introduced in the extracts which might influence the response of the test preparations to oxytocin and antidiuretic hormone This is important in relation to estimating the ratios of endogenous hormones in blood under various conditions

Summary

An improved method is described for extracting oxytocin and antidiuretic hormone from blood

In a series of experiments in which posterior pituitary lobe extract, oxytocin, or vasopressin was added to blood and extracted, the mean recoveries of oxytocic and antidiuretic activity were 77% (S E ±5 01) and 68% (S E ± 5 38) respectively, compared with recoveries of about a third in the original method

Metals in Bone Surgery

A MEETING of the section of orthopædics on May 7, with the president, Mr STANLEY EVANS, in the chair, discussed the use of metals in bone surgery

Mr G K McKEE (Norwich) said that the history of the use of metals in bone surgery was not a happy one The use of unsuitable metals had marred the work of Lane and Lambotte, but interest had been revived by Smith Petersen's use of a stainless steel trifin nail in fractures of the neck of the femur

Two problems faced the orthopædic surgeon today —to prevent corrosion phenomena in his appliances and to determine indications for the use of different appliances These problems were closely related because the indications for the use of metal would increase as corrosion rate decreased when more suitable metals or metallic alloys were found

Tests were carried out to compare the relative rates of electrochemical attack on two different types of stainless steel and on the non-ferrous alloy 'Vitallium' If two different metals were in contact and were immersed in an electrolyte such as the body-fluids, one metal would become electrically positive to the other Cl ions in the electrolyte would migrate to the negative metal or anode and give rise to chemical attack Some metals, such as those under consideration, tended to form oxide films which had a high resistance to penetration by ions It had been established that the presence of molybdenum in an alloy was an aid to the establishment of a barrier film of oxide

If two identical metals were used to form the cell then no electrical potential difference was created between them, no current flowed, and there was no attack In practice it was virtually impossible to produce metal components of identical material Plates and screws, for example, would be produced from different metal stocks, and although of the same nominal composition there would inevitably be some slight differences Surface working during machining operations would itself create some degree of electrical potential It was this creation of a passive oxide film on the anodic metal that must therefore be the main barrier against corrosion

The recommendation was, therefore, that if stainless steel was used for internal fixation it should contain $2^{1}/_{2}$–$3^{1}/_{2}$% molybdenum The non ferrous chromium cobalt molybdenum alloys (vitallium or 'Vinertia') were quite free from corrosion Plates and screws made of the same stainless steel would corrode but less rapidly if they contained $2^{1}/_{2}$–$3^{1}/_{2}$% molybdenum The screw was anodic and therefore suffered greater attack than the plate Vitallium screws used with a stainless steel plate were not attacked, the plate, however, being anodic, did show some effects of corrosion

The most resistant type of stainless steel, known as F M B, appeared in practice to be quite satisfactory where the fixation was only temporary as in fractures and arthrodesis operations Where a permanent functioning insert was required, however, then the apparatus must be made up of a non-ferrous chromium cobalt-molybdenum alloy

Mr McKee described the development of an artificial hip joint The earlier model (1951) was in stainless steel It was satisfactory for several years but later failed because the steel corroded and the plate broke some 3½ years later Since then the apparatus had been redesigned for manufacture in an inert alloy, and it now appeared to be very satisfactory since no corrosion had occurred It was a complete replacement ball-and-socket joint for the hip, and was particularly indicated for hip-joint surgery when the acetabulum was grossly eroded It had, therefore, been used largely when failed acrylic prostheses had given rise to changes in the acetabulum

Mr John Charnley (Manchester) thought that electrolytic phenomena in metal appliances were of considerable importance only with long-term inserts Over short periods mechanical stress was a commoner cause of loosening Stress was a cause of corrosion too, because under its influence even high-quality steels suffered a deformation of their investing film of oxide The molecules of the film were wrenched apart and ionic penetration became possible

In the response of bone to metals, three situations deserved consideration when the inserted metal was not transmitting any stress, when it was transmitting stresses and was moving slightly, and when the metal transmitted stress without moving An example of the first case was the plate across a fracture which had united Such devices did not loosen on the contrary, they might be very difficult to extract because new bone gripped the holding screws very tightly And this was true of highly polished stainless steel screws as well as of matt vitallium ones An insert which was moving slightly under stress always became gradually looser Such a change was to be seen in a Steinmann pin pulling on a fractured femur. This loosening seemed to predispose to infection, as Hey Groves observed when he tried to fix experimental fractures with short plates which permitted a little movement in place of long ones When stress was transmitted to bone by a metal insert which was not moving, it did not excavate the bone about it Cortical bone was very resistant even to immense strains if they were of constant direction, as for instance when a compression clamp was applied across a joint undergoing arthrodesis, the device did not become loose Bone responded primarily to the application of stress by osteogenesis over a long period, continuous pressure induced remodelling, which was a balanced process of osteoclasis and osteogenesis

Mr J H Hicks (Birmingham) suggested that in the past inflammatory processes caused by corrosion of metal had not been adequately distinguished from those due to infection The changes induced by corrosion closely resembled those of bacterial infection and the granulation tissue at the site of an unsuitable insert often looked typical of infection, but the lesions proved to be sterile The common cause of such reaction was the use of corrodible steels some stainless steels provoked reactions sometimes even without contact with a dissimilar metal The use of these steels might give rise to unfortunate sequelæ which could not be prevented by any "no touch" technique, however rigid Once it was realised, however, that bone in the presence of metal inserts had no peculiar susceptibility to infection, it was logical to extend the benefits of internal fixation to compound fractures And it had in fact been found at the Birmingham Accident Hospital that extensive use of metal devices in securing open fractures had not been followed by an increase in the incidence of infections With the disappearance of the hazards of bad metal, the pre eminent problem was now that of skin necrosis and sloughing

Discussing some engineering problems in the design of metal inserts, Mr J M Zarek, PH D (King's College, London), pointed out that the resistance of metal to corrosion was influenced by the way in which it was polished The extent to which different screws changed could be related to the shape of their threads Areas where stress concentrations were high corroded early, particularly when screws and plates were not perfectly co apted to each other

Mr Norman Capener (Exeter) spoke of the desirability of standardising as soon as possible at least one acceptable combination of plate, hole, and screw

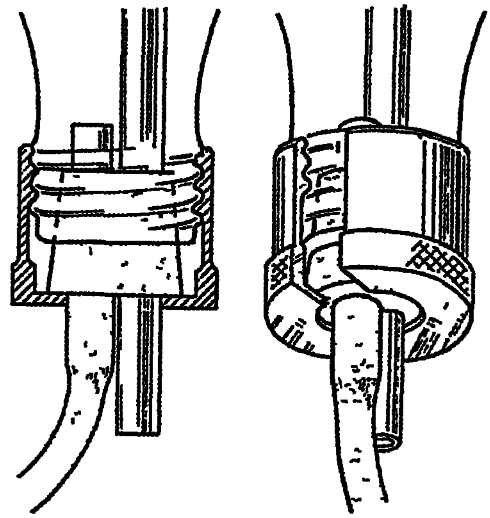
Dr J T Scales (Stanmore) described an investigation into the extent of corrosion in a large number of metal appliances Corrosion was commonly worst at the screw-countersink interface, and was conspicuously absent in chromium-cobalt molybdenum alloys

New Inventions

A SIMPLE METAL RETAINING CAP FOR THE STANDARD NATIONAL BLOOD TRANSFUSION SERVICE GIVING SET

The mantle of the standard blood-transfusion giving set is normally held in position by a rubber stopper inserted firmly in the neck of the glass bottle There is always a danger of the stopper slipping out, particularly in the operating-theatre if positive air-pressure has to be applied to the infusion to increase the rate of delivery

The usual method of preventing this is to tape the rubber stopper in position with adhesive strapping This is cumbersome, whereas the device described here is simple A small metal cap fits over the rubber stopper and screws on to the neck of the bottle The cap has a small round hole in its top through which pass the outlet and inlet tubes The hole is slightly smaller than the diameter of the rubber stopper, which is thus supported round its perimeter A small slit in the side of the cap allows it to be easily slipped over the rubber tubing Once the mantle of the giving set is firmly inserted into the bottle, the cap is readily screwed into position, preventing the rubber stopper from being dislodged



I am indebted to Mr E G Smith and Mr A T Smith, of the Guy s Hospital Medical School workshop, for making the cap, and to Miss M J Waldron, of the department of medical illustration of Guy s Hospital, for the diagrams The cap may be obtained from A Charles King Ltd , 27, Devonshire Street, London, W 1

Reviews of Books

Movement of the Heart and Blood in Animals

An Anatomical Essay by William Harvey Translated by KENNETH J FRANKLIN, D M, F R C P F R S, professor of physiology, University of London Oxford Blackwell Scientific Publications 1957 Pp 209 17*s* 6*d*

THIS new translation from the Latin text of *De Motu Cordis* was first suggested by Prof John F Fulton as an appropriate contribution to the tercentenary of Harvey's death The idea commended itself to the president of the Royal College of Physicians and at his invitation Professor Franklin undertook the task Earlier versions were not sufficiently accurate for those doing either historical or experimental research upon the circulation The new translation and the Latin text are each preceded by a title page suggesting that they represent the text of the Frankfurt edition of 1628, whereas it is stated in the preface that the text used is the 1766 edition, presumably the *Opera Omnia*, published in London This edition was very carefully prepared, and at the end of the section containing the writings on the heart there is a list of 246 corrections made to the original edition [1] There are therefore differences between the Latin texts of 1628 and 1766

The translator and his sponsors at the Royal College are to be congratulated on a first-class book that will appeal to a new generation of readers Let them read for themselves Harvey's indignation at the old theories ("Good God! How do the mitral valves hinder the return of air and not of blood?") and the way in which he reaches his final statement

> "I am obliged to conclude that in animals the blood is driven round a circuit with an unceasing, circular sort of movement, that this is an activity or function of the heart which it carries out by virtue of its pulsation, and that in sum it constitutes the sole reason for that heart's pulsatile movement"

Surgery of the Anus, Anal Canal and Rectum

E S R HUGHES, M D, M S, F R C S, F R A C S, surgeon to outpatients, Royal Melbourne Hospital, Melbourne Edinburgh E & S Livingstone 1957 Pp 304 50*s*

A MEASURE of the esteem in which St Mark's Hospital is held is the speed with which its doctrines—anatomical, pathological, or clinical—become part of orthodox surgical practice Mr Hughes's book bears the stamp of St Mark's and cannot, therefore, be provocative or even novel, but it embodies much valuable research done by the author himself

With Goligher, he demonstrated the importance of the rectal mucosa in the initiation of bowel sensation—an important argument in the current controversy over restorative resection for high rectal cancer (Of the controversy itself the book contains a balanced and critical account and the description of the operations is admirable) Immediate skin-grafting after excision of anal fissures and fistulæ is another attractive proposition that Mr Hughes put forward some years ago Although the procedure may seem to transgress surgical principles, scepticism will be disarmed by the detailed and convincing way in which it is presented

Some readers will be disappointed when Mr Hughes disclaims sufficient experience to dogmatise on one or two difficult therapeutic problems (such as the management of high rectal fistulæ), but this attitude is the correct one and strengthens confidence in what Mr Hughes says elsewhere in the book Throughout his aim has been to guide rather than to pontificate and he dwells on the difficulties which the average surgeon may meet rather than on his own mastery

The most important criticism applies to most monographs whose subject is anatomically rather than functionally circumscribed—namely, the book cannot adequately deal with conditions which affect the region but show no respect for its boundaries Thus proctitis cannot be properly discussed without more fully considering ulcerative colitis and even familial polyposis of the colon and rectum may only be part of a more widespread disease

The historical illustrations with which the text is embellished are pleasing, but the biographical notes are rather less successful, and a critical survey of the growth of proctology might have been more illuminating Perhaps such a chapter may be added to future editions—for which there should be a steady demand

The Doctor as a Witness

JOHN EVARTS TRACY, professor of law (emeritus), University of Michigan Philadelphia and London W B Saunders 1957 Pp 221 30*s*

Professor Tracy is a senior member of the American legal profession and necessarily writes with a background of United States law His book shows clearly how the qualities required of an expert witness, and especially of the doctor, are the same under any legal system The types of legal proceedings in which the doctor may be involved are described, and the question of opinion evidence and the expert witness is examined in detail It is evident that in the United States preparation of a case is expected to be more thorough than is customary in Britain This work makes fascinating reading and can be recommended to any graduate in medicine or law

Simulium and Onchocerciasis in the Northern Territories of the Gold Coast

G CRISP, B SC, PH D, director, entomological unit, British Empire Society for the Blind London H K Lewis, for the British Empire Society for the Blind 1956 Pp 171 57*s* 6*d*

IN 1952 two teams of experts, one entomological and one ophthalmological, were sent to the Gold Coast by the British Empire Society for the Blind to work on the problem of onchocerciasis, then only recently recognised as one of the worst of the many community scourges of the hinterland Dr Crisp's entomological report is the first of the two to be published He gives a clear description of hard methodical work on all aspects of simulium ecology in the area He is almost overcautious in making deductions from the great amount of data he has assembled, for example, it was not *proved* that the fly's survival of the dry season takes place in adult form, but his experiments make it very likely The scientific honesty of Dr Crisp's writing is notable

To anyone working on simulium or onchocerciasis in West Africa the monograph is an essential guide Laymen interested in the subject or the country will find it understandable and easy to read Dr Crisp and the society are to be congratulated

An Atlas of the Commoner Skin Diseases (5th ed Bristol John Wright & Sons 1957 Pp 384 105*s*)—A new edition of Dr Henry Semon's book will be welcomed by those who often feel the need for a good atlas of common skin diseases It has been prepared in collaboration with Dr Harold Wilson 16 excellent new plates have been added to an already good set of illustrations Too much space has perhaps been given to the now comparatively uncommon disease, lupus vulgaris, including two plates illustrating the rarer form, lupus verrucosus The omission of molluscum sebaceum from the fourth edition has been remedied, but too little attention is given to squamous celled carcinoma, and the term 'epithelioma' is treated as synonymous with rodent ulcer Many new methods of treatment have been added but some of the outmoded ones are given more prominence than their successors

Recent Advances in Anæsthesia and Analgesia (8th ed London J & A Churchill 1957 Pp 295 40*s*)—Dr J Alfred Lee has joined Dr C Langton Hewer in producing the new edition The subject matter has been completely revised and, without doubt the book now represents the most up to date and useful work of reference to the latest developments in anæsthesia

Venoms (Washington, D C American Association for the Advancement of Science London agents Bailey Bros & Swinfen 1956 Pp 467 86*s*)—The papers given at the first international conference on this subject which was held in 1954 at the annual meeting of the American Association for the Advancement of Science have been published under the editorship of *Eleanor E Buckley* and *Nandor Porges*

THE LANCET

LONDON SATURDAY, JUNE 8, 1957

Walls of Jericho

BEFORE mental illness we have been comparatively helpless, and the public attitude towards it has reflected the fear and suspicion which helplessness often breeds. The law, in an honest endeavour to protect both community and patient, has by its complexity and caution often increased public prejudice and unnecessarily restricted the liberty of the individual. But in the last decade or two, new methods of treating mental disorder have altered the picture. Our mental institutions are becoming, in fact as well as in name, hospitals instead of asylums, and with success in the treatment of acute illness fresh efforts are being made to restore health to patients who have been ill for a long time. Despite overcrowding, shortage of staff, and old-fashioned buildings and equipment, the emphasis is changing from custodial care to therapy; and more and more patients are enabled to return to their homes or to lead more normal lives in the hospital. These changes have had their effect on the public, which is beginning to accept mental illness as a disability comparable to physical illness. In this new climate of opinion it became apparent that the law relating to mental disorder must be reconsidered, and in 1954 a Royal Commission was appointed under the chairmanship of Lord PERCY OF NEWCASTLE. The commission's recommendations (summarised on p. 1187) are based on the principle that the mental patient should have access to the health and welfare services as freely and with as little formality as any other patient. Many of the so called safeguards of the present law not only are unnecessary but are a barrier between the patient and the help he can be given.

Today, of course, most patients are admitted to hospital with their own consent; yet every year some 20,000 are certified—often only because they are unable, because of their illness, to fill in the necessary form. The commission believe that, unless a patient refuses to go to hospital, we should assume that he agrees to treatment. The law should regard this as the usual procedure, and the use of compulsion, though sometimes necessary in the patient's interests, should be exceptional. Even for these cases, "certification" should be discontinued in favour of a medical recommendation authorising a hospital to accept the patient for treatment; and if the hospital finds itself unable to provide suitable treatment it should be allowed to refuse to accept the patient. The emphasis would thus be on the clinical needs of the patient and not on his segregation. The recommendation for his admission would ordinarily be signed by a psychiatrist and the family doctor. The present procedure of calling in a justice of the peace is not only ineffective as a safeguard but inappropriate; and such intervention by the law is one of the reasons why relatives find certification so distressing. This prejudice may be unreasoning and unreasonable, but it is deep seated; and the commission speak of the common belief that certification implies illness so grave that a patient is "really mental" and will never completely recover. From the hospital's standpoint, too, admissions are needlessly complicated by protocol. Thus a "designated" hospital cannot accept a patient unless the legal niceties are observed; and as an escape from the complexity of the system, some hospitals have had to create (with good intent if barbarous language) "dedesignated" villas and beds. For the past few years hospitals for mental defectives have been encouraged to accept some children without certification, and the commission would like to see this practice extended, without waiting for further legislation. Many parents are understandably reluctant to part with their child if they feel that they are formally resigning their rights over it.

The commission have recognised how untrue it is to say that "names will never hurt you." To patients and relatives much of the blunt terminology of the Mental Health Acts is unnecessarily wounding. "Idiot" and "imbecile" are offensive to many; "moral defective" is often misunderstood. A new name is often said to attract the odium of the old; but at this time, when the public attitude to mental disease is changing, the commission feel that it would be worth introducing a fresh terminology that will not only be free of unhappy associations but also be readily understood. The three new groupings which they suggest for patients—mentally ill, psychopathic, and severely subnormal—are for broad administrative purposes and, they insist, not "labels for life." Their use of the word "psychopathic" for patients with a personality disorder is wider than is customary, and it is, as they admit, not altogether happy. To those familiar with popular "psychiatrese" it has criminal associations; for the less sophisticated it will be a difficult and unfamiliar word.

In Parliament, the courts, and the press attention has lately been drawn to patients who are said to have been improperly detained in hospital or under licence. The commission, not unexpectedly, had some evidence of this kind submitted to them, which they found useful as an indication of public fears, against which the present Acts, for all their complexity and however justly administered, do not offer sufficient safeguards. To allay public doubt on this score they propose that regional mental-health review tribunals should be set up to which patients and their relatives should have ready access. This shift of control from the centre to the periphery should also, the commission suggest, apply to the scrutiny of documents. These changes, and the sharp reduction in the use of powers of compulsion, would end the work of the Board of Control, already greatly reduced since 1948 when the Ministry of Health took over the general supervision of mental-health services. The board in its evidence to the commission committed administrative hara-kiri, for it supported the very changes which, when they become law, will end its own life.

The findings of the commission recognise another shift of emphasis, this time from the hospital to the community.[1] They suggest that the local health authorities should assume full responsibility for the preventive and aftercare work of the mental-health service The commission look forward to a time when the hospitals will look after only those patients who need specialist treatment or training or continuous nursing The local authorities will then provide not only social services, to help and support patients who return to their families, but also residential homes and hostels for young subnormal and psychopathic patients and for the elderly who are mentally infirm This change would succeed only by joint endeavour by the hospital and the local authority Nottingham has already shown that this can be achieved even within the present more rigid administrative framework [2]

---

[1] See *Lancet*, 1956, ii, 1087.

The return of the patient to the community, either to his home or to some small hostel, will depend not only on administration It will depend also on his acceptance by the community and on their willingness to welcome him with as much sympathy as they do the physically handicapped The recommendations of the commission, when given their legislative due, will speed the day when this change in public attitude will allow the mental-health service to fall into its proper place in the pattern of the health services of the country At present the law, like the over-heavy fortifications of an enclosed city, cuts it off from the outside world After a careful survey of the obsolete ramparts the commission have called for their demolition They have sounded their trumpet loudly, and it is up to doctors, patients, and public to join in the fanfare that will make these walls at last come tumbling down

Medical Education the New Freedom

THE profession in this country is sometimes charged with producing wise words and reports on medical education, while stopping short of actual reform, so it is perhaps worth stating that our medical schools have made substantial progress in the past decade Following the direction given by the Goodenough report in 1944, the smaller schools have been enlarged, full-time university units in clinical subjects have grown and multiplied, and introductory courses of various patterns have been devised to link preclinical with clinical teaching Responsibility for vocational training has been partly transferred from the undergraduate course to the preregistration year The standard of clinical care displayed before the students has risen immeasurably through the growth of medical teams, in which the oracular pronouncements of the consultant to his houseman are largely replaced by informal discussion in a group—a group in which the awesome gap between senior physician and new boy is filled by lecturers and registrars, not all of whom are the "angry young men" of popular report The vital contributions of the laboratory technician, the radiographer, the pharmacist, the social worker—all the members of the Greater Medical Profession—are now so much a part of medical care that the student need no longer be cajoled into noticing them And all these things have been done in medical schools built for fewer students, and in hospitals at least twenty years old

This evolution in medical education has been paid the compliment of criticism of many kinds, the expected balance between the cries of "Too fast" and "Too slow" is somewhat upset by dissonant voices claiming that we are moving in the wrong direction entirely Though Babel cannot be summarised, perhaps we can discern behind it all a conflict of principle between those who emphasise practical and vocational training, and those who favour a liberal scientific education When it comes to method, the trainers pin their faith largely to didactic instruction, including substantial lecture courses and a rigid examination system, while the educators are experimenting with discussion groups, seminars, modified tutorial arrangements, and interdepartmental classes But trainers and educators alike believe that the student should spend more time with patients, both in the wards and under conditions approaching those of general practice, and they also unite in deploring any further adventitious addition to the curriculum While the main hindrance to reform has no doubt been the conservatism of medical faculties and the jealous guarding of departmental prestige, the would-be reformers have also been hampered by the excessive precision of many of the *Recommendations* on the medical curriculum issued by the General Medical Council in 1947 They will be all the more disposed to welcome the new *Recommendations*, approved last week, which are shortly to be circulated to medical schools Both this document itself, and the introductory statement which accompanies it, are informed by a new spirit of freedom most grateful to those who, like ourselves, hold that a doctor must not be a certified technician but an educated man capable of assessing and applying new knowledge and of helping his patients by his personality as well as by his technical skills

Instead of taking its decennial opportunity to add to the tasks of student and teacher, the council has generously accepted the criticism that its 1947 *Recommendations* "were too detailed and precise, and left insufficient scope for the exercise of initiative and experiment on the part of Licensing Bodies and of Schools" (A good deal of the credit for making this widely felt criticism both manifest and powerful must go to the Royal College of Physicians of London, which has presented its views to the council [1] and has also helped to prepare for the future by convening the conference on medical education held last November) The welcome change in outlook is well seen in a paragraph which says that the new *Recommendations* "indicate the minimum length of the whole period of professional study, but refrain from specifying the period of time to be allotted to particular subjects and the sequence in which they should be taught Specialties and subdivisions of the principal subjects are no longer specified, and no attempt has been made to indicate precisely the scope of the instruction which should be given in particular branches" Though the council has examined carefully the possibility of reducing the length of the curriculum, it has (in our view correctly) decided against doing so at present On this its main argument is that the primary need is to reduce congestion —"to instruct less and to educate more"—and if the curriculum were simultaneously to be shortened "the principal object of the proposed reform would be thwarted"

---

[2] Macmillan, D *Ibid* p 1091

[1] *Lancet* 1955 ii 132 *Ibid*, 1956 i, 437

Under Sir **David Campbell**'s leadership, the council has thus taken a notable step away from restrictive practices But, having obeyed the classical injunction *Primum non nocere*, it must now look to the individual medical schools for the fruition of the new opportunities A statutory nation-wide council can create the conditions for reform, but cannot itself take positive and specific action towards it The council is making its experience available to medical schools in the form of "notes ' added to the different *Recommendations*, and it hints that medical schools may in future be "visited ' more frequently and less formally, by small groups—a practice which, though it originates in the need to safeguard the public, could develop into something also very useful to the schools themselves Responsibility for improvement has now been definitely thrown back, however, to the universities, which are encouraged to consider as soon as possible what use they can make of it To expect that all will want to experiment would be unreasonable, and the merit of the new arrangements is that they allow different ways of teaching to be used simultaneously in different schools But we shall be much surprised and disappointed if three, four, or half a dozen do not rise to the new challenge to show that they can do better, or at least have the spirit to try We trust that the individual schools in London will not be denied this chance

Macewen's Eternal Triangle

Nowhere is the influence of antibiotics on surgical techniques better seen than in the treatment of cerebral abscess Until the advent of efficient antiseptics compatible with living tissues, methods of dealing with intracranial infection were designed to prevent a fatal spreading meningitis[1] The methods were extremely varied, and their relative merits were hotly contested Simple aspiration followed later by excision vied with tube drainage and even with marsupialisation Reports published within the past ten years show, by contrast, a remarkable unanimity of approach The aim is to aspirate the abscess at the earliest possible moment through a clean field and to insert a wide-range antibiotic or a combination such as penicillin and streptomycin, together with about 1 ml of 'Thorotrast' This completes the first operation As soon as an organism has been grown and its sensitivity has been established—which takes about forty-eight hours—the specific antibiotic cover is introduced The abscess is aspirated every two days or at longer intervals, according to progress, until the pus is sterile and the thorotrast shadow no longer enlarges again after aspiration As it is observed over the subsequent weeks it should shrink progressively until it represents only a small crenated scar If the contents do not become sterile or if the abscess does not collapse excision is undertaken[2]

This regime is also applied with modifications in subdural and epidural collections of pus Provided the correct antibiotic is found in time and administered in adequate dosage, the results are excellent—though a subdural collection alongside the falx may cause diagnostic difficulties, best resolved perhaps by the maxim Pus somewhere, pus nowhere, pus alongside the falx (It is of help to remember that subdural pus tends to spread under the influence of gravity) The therapeutic miracle of yesterday has today become the commonplace, and even intraventricular rupture of an abscess is no longer invariably fatal, if specific therapy is instituted immediately at first by intraventricular instillation But deaths still occur from these disasters, from spreading encephalitis (usually due to pneumococcus or streptococcus), and from multiple abscesses It should be remembered that hæmatogenous abscesses are not necessarily multiple, but that a high proportion of them, associated with a cardiac abnormality, are ' paradoxical '[3]

The signs of intracranial lesion together with those of an infective illness suggest the diagnosis, which may be confirmed by finding an increased number of cells or increased protein in the cerebrospinal fluid or a raised erythrocyte-sedimentation rate Electroencephalography is of help in differentiating an intracranial abscess from a more widespread lesion, and ventriculography or angiography may be necessary Management of the very acute stage of encephalitis remains debatable Sucking out the infected area[4] has not been regarded with sustained enthusiasm, and the stoutest friend of the surgeon here is undoubtedly the correct antibiotic In some centres the abscess is later excised routinely, unless it lies in an unsuitable site—for instance, near a speech area It is still doubtful whether excision of a completely sterilised abscess scar reduces the likelihood of subsequent epilepsy

Gurdjian and **Webster**[5] conclude from their series that the incidence of cases due to ear infection is decreasing in the U S A and from this series it might be inferred that the intracranial sepsis secondary to ear infection is largely preventable In this country, on the other hand, **Pennybacker**[6] did not find that otogenic cases were diminishing, they represented in his series over 40% of all brain abscesses **Pennybacker** plead strongly for an investigatory approach to intracranial sepsis through a clean field Anyone with any experience of this problem admits that the intracranial abscess is occasionally unpredictable A negative exploration " of a septic cavity in which the flora is unknown frequently leads to spreading infection, which is all the more tragic because it is due to the treatment rather than the disease **Crabtree**[7] says In earlier days brain abscesses were explored through the infected mastoid wound We never dream of doing this now, any intracranial exploration being through an independent clean field It would be another step forward if we could limit ourselves in the treatment of lateral sinus thrombosis to a meticulous clearance of extradural disease, except perhaps for excision of a rare intra-sinus abscess " To the mastoidectomist the dura represents a Halt sign which he crosses at his patient's peril On the other hand, an otogenic abscess should be treated by an adequate mastoidectomy as soon as the patient's condition permits—usually within four or five days Only by intelligent cooperation between the neurosurgeon and the otologist can the best results be obtained in the treatment of cerebral sepsis

Annotations

THE HARVEY TERCENTENARY

Last Monday was the tercentenary of the death of William Harvey In London there was a commemoration service at St Paul's Cathedral arranged by the Royal College of Physicians, the congress organised by the Harveian Society of London opened at the Royal College of Surgeons, and throughout the week the occasion has been celebrated in various ways by a re examination of ideas old and new about the circulation

The congress has been discussing some of the latest physiological and clinical developments in the study and treatment of circulatory disease, and we hope to record some of the proceedings in our next issue At the week end the scene will change to Folkestone, where Harvey was born in 1578, and where the congress will hear accounts of Harvey's life and work in its different stages

The Royal College of Physicians has sponsored an excellent new translation by Prof K J Franklin, of *De Motu Cordis* (to which we refer on p 1176), and a new edition of the colour film about Harvey and the circulation has been on view at the college

In the film Sir Henry Dale explains that this is a remake of the earlier black and white silent film which he made in 1928 with the late Sir Thomas Lewis While Sir Henry is tracing the dates and events of Harvey's life, the camera occupies itself with old prints and drawings, many of which were on view at an exhibition in the college library During readings from *De Motu Cordis*, the film demonstrates, from animal experiments and clinical observations, the facts on which Harvey based his deduction His delightful descriptions are beautifully illustrated The colour photography is of the high quality customary from the Wellcome Film Unit, who produced the film [1]

Among the other activities of a busy week in London was an exhibition illustrating Harvey's life and ideas, which has opened at the Wellcome Historical Medical Museum, and on Thursday the British Cardiac Society held a special meeting at the Royal College of Surgeons

THE COST OF AMERICAN MEDICINE

The cost of medical care continues to exercise the minds of the American people, and the situation is discussed in an article in the *New York Times* [2]

Although some two thirds of the population of the United States have some form of medical insurance (often included as fringe benefits in a trade union contract) this does not by any means always pay the whole cost of a serious accident or illness Indeed, it meets only about 25% of the big bills, for comparatively few schemes afford full cover Some pay bills up to a certain sum, others bills beyond a certain sum, but in either case the patient pays the rest For mental disease and tuberculosis, which many policies exclude, free treatment is commonly provided by individual States, but other long term illnesses are sometimes not covered, and benefit often ceases at the age of 65 American opinion is divided on whether a comprehensive health system would cost more than what medicine is costing now—which is estimated at some 4–5% of the total national income Meanwhile hospital charges continue to rise, and the need is particularly felt for insurance that can be paid for during the healthy middle working years and that will provide for old age, as well as for the children of the insured

According to the *New York Times* writer, many physicians are wary of change and pessimistic about the future, and relations between physicians in various medical specialties, and between other workers in health fields, are more strained than they were "there appears to be less concern about putting up a solid front for the public and more real competition for patients and insurance fees" Many practising doctors hold that it is not their responsibility to plan health services, and they do not like to "get into politics", but "the prevailing widespread opinion is that physicians—and not many others in health fields—are lagging in planning the future of the health services system in the nation" It seems clear that in the near future public opinion is going to demand more readily available medical care

POLIOMYELITIS VACCINATION

Last year was a comparatively mild one for poliomyelitis and that is one of the reasons why it has been hard to assess as fully as was expected the degree of protection conferred by the British vaccine which was given to 210,000 children in May and June, 1956 Moreover, supplies of vaccine were not as ample as had been hoped for and there was little time—only six weeks—in which to give it before vaccination was stopped at the end of June Vaccination was restricted to children born in the years 1947–54 Nearly 400,000 injections were given and there was no evidence that they had been accompanied by any mishap The number who completed the course of two injections was 148,684 In this group the protection was of the apparent order of 80%—very similar to that observed in the 1954 trial in the United States Discussing the results at a meeting of the section of epidemiology and preventive medicine at the Royal Society of Medicine on May 31, Dr John Knowelden, secretary of the Medical Research Council's poliomyelitis vaccines committee gave these figures for all forms of *paralytic* disease, the onset of which fell between July 1, 1956, and Jan 31, 1957

The attack rate of those illnesses reported as non paralytic poliomyelitis did not seem to be affected by vaccination The findings are set out in detail in the report [1] of the poliomyelitis vaccines committee

In 1955 the M R C's committee on safety tests of poliomyelitis vaccine advised against the inclusion of the virulent type I Mahoney strain in the British vaccine, and the less virulent Brunenders strain was used as the type I representative in the vaccine prepared by Glaxo Laboratories Despite the small number of observations, it seems clear that the Brunenders strain is able to protect against the kind of type I infections that were prevalent in Britain last year, and that the vaccine also protects the younger children

That this and other vital information has been obtained so quickly, despite the enormous difficulties and the vast amount of work involved, is a striking achievement The vaccine protects the most important of the questions still unanswered is for how long it protects

PENICILLIN MODE OF ACTION AND CHEMICAL SYNTHESIS

Earlier indications that the mode of action of penicillin on gram positive organisms is specifically on the cell wall have been confirmed [2] Penicillin inhibited cells were found to accumulate uridine nucleotides in the cytoplasm,[3] and elucidation of the structure of these compounds has shown the principal one to be uridine 5' pyrophosphate linked through a hitherto unknown sugar (3 O carboxyethyl hexosamine) to a pentapeptide of D glutamic acid L lysine and DL alanine

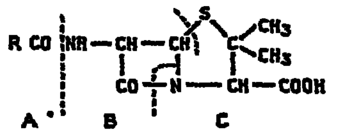
D-glutamic acid – DL-alanine O CO
L-lysine – DL-alanine – DL-alanine

As the peptide hexosamine fragment is almost certainly identical with an important part of the structure of the bacterial cell wall,[4] penicillin probably acts by interfering with the transfer of this fragment from the uridine pyrophosphate to the acceptor site on the cell wall The use of this uridine nucleotide in transferring units of monosaccharides in polysaccharide synthesis, and of units of glycerides for lecithin synthesis, has been well established

Reaction mixtures containing minute traces of penicillin activity were prepared in 1944, both in England and in the United States, and painstaking isolation procedures showed that the active moiety in such mixtures was indeed penicillin[5] But such a synthesis, interesting though it was, had no value in the production of new "unnatural" penicillins, nor for proof of structure of this sensitive molecule Professor Sheehan and his colleagues[6] at the Massachusetts Institute of Technology have just crowned ten years' work with an elegant synthesis of penicillin V This follows suggested biosynthetic pathways which envisaged the molecule as derived from an acid residue (A) linked through α-formylglycine (also known as amino-malonsemialdehyde) (B) to penicillamine (C)



The protected amino-malonic ester semi-aldehyde (I) condensed with D penicillamine (II) to give the thiazolidine (III) The amino group was uncovered and condensed with the appropriate acid residue to give (IV) The ester group was removed without further rupture of the molecule, and water was then eliminated by reaction with dicyclohexylcarbodiimide (DCC) to complete the 4 membered lactam ring in (V), which product was shown to be identical with natural penicillin V The reactions devised were all carried out at or below room-temperature to avoid breakdown of the unstable ring structure

TUBERCULIN TREATMENT IN PULMONARY TUBERCULOSIS

SINCE 1890, when Koch first suggested its use in therapy, tuberculin has been widely if inconsistently used in treating various forms of tuberculous disease Success has been claimed from time to time with lesions of the eye and skin, and tuberculin still enjoys a vogue on the Continent, particularly in France, but clinical impressions do not seem to be supported by controlled statistical studies In this country tuberculin has had its most striking success as an adjunct to chemotherapy in the treatment of tuberculous meningitis At Oxford, Smith and Vollum[1] administered the purified protein derivative (P.P.D.) intrathecally to three patients with tuberculous meningitis in whom the prognosis seemed hopeless, in all three an unprecedented improvement followed, and two recovered permanently and completely, the third patient died, but at necropsy it was found that the exudate surrounding the mid-brain had resolved These findings have been confirmed,[2] but P.P.D therapy is not held to be necessary or desirable in all cases of tuberculous meningitis, for when the disease is detected early patients make excellent recoveries with chemotherapy alone

In pulmonary tuberculosis there was no convincing evidence before the introduction of chemotherapy that tuberculin was effective, but in 1955 Madigan and Young commented favourably on its clinical effects, and Howells and Swithinbank[3] have described a pilot statistical trial done to determine whether tuberculin in association with streptomycin and *p* aminosalicylate (P.A.S.) had any therapeutic value The investigation, carried out in Bantu patients at Durban, suggested that those treated with chemotherapy plus tuberculin had a limited advantage over those treated by chemotherapy alone The advantage held only up to the 30th week of treatment and was most manifest in the worst cases, where it was statistically valid Howells and Swithinbank attribute the improvement to hyperæmic reactions (caused by the tuberculin) in the tuberculous lesions, allowing the antimicrobial drugs increased access After the 30th week these reactions, which were of course accompanied by symptoms and fever, tended to become fewer and less pronounced, and the fact that after this time no improvement in results, compared with the controls, was evident, suggests that the thesis is at least partly correct But improvement under tuberculin therapy has also been ascribed specifically to its desensitising property, and according to this view tuberculin negativity should be maintained indefinitely The Durban study does not seem to support this hypothesis

Tuberculin treatment is apparently free from serious danger, but it entails a certain amount of discomfort for the patient from the reactions it produces, and (especially if continued over years as outpatient therapy) it involves time off work for the patient and a considerable organisational effort by the chest clinic There seems to be no strong case for using tuberculin as a routine It may yet be shown to be useful where the lesions are recalcitrant to ordinary methods—for instance, those with organisms becoming resistant to chemotherapy But it has not yet been proved to give a satisfactory response in the chronic, fibro caseous type of lesion which commonly produces resistant organisms, and for the early acute lesion the administration of cortisone in association with chemotherapy seems preferable

APARTHEID IN NURSING

THE Amending Bill[1] to the Nursing Act, which the South African government has introduced during its present parliamentary session, fits logically with the Bantu Education Act and the Separate University Bill into the pattern of apartheid There are to be separate registers for white, coloured, and native nurses, special examinations may be arranged for each group, and different uniforms may be worn There is no room for doubt in this case that the non-European nurses are to have an inferior status, for the Bill specifically lays down that the South African Nursing Council shall have white members only, and only white nurses may vote for the elected posts on the council Advisory boards are to be established for coloured and native nurses but with limited functions All nurses are bound by statute to join the South African Nursing Association, but under the Amending Bill meetings of white, coloured, and native members of the association will take place separately The Bill lays down that "a decision of the majority of the members of the Association present at any meeting held under this Act, by members who are white persons, shall constitute a decision of the Association," while decisions taken at meetings of non-white members are considered as recommendations only The controlling board of the association is to consist of white members only and the electorate for board members are all to be white Non whites may elect advisory committees, again with limited advisory functions

A later clause of this Amending Bill is aimed at the non European doctor and his relationship with nursing staff "Any person who causes or permits any white person who is registered or enrolled to be employed under the control or supervision of any person who is not a white person, in any hospital or similar institution or in any training school, shall be guilty of an offence and liable on conviction to a fine not exceeding two hundred pounds"

A recent letter to the *South African Medical Journal*[2] shows that non European nurses are fully alive to the implications of the Bill and fear for their status, and indeed for the standard of nursing, which they feel is at stake, in the non European hospitals It is also clear that these nurses, although legally compelled to be members of the Nursing Association, have no official voice, and were not enabled to give evidence to the Select Committee which drafted the present amendment What does seem surprising is that both the South African Nursing Council and the South African Nursing Association, in their evidence to the Select Committee, favoured racial discrimination, and are not at present voicing any dissent to the Bill The South African Nursing Association is affiliated to the International Council of Nurses, and to avoid prejudicing this international tie, its board proposed[3] not separate associations for the different races but a single (white) association, in control of a standing committee representing non-white nurses Though it had taken only a limited canvass of association members, the board gave evidence to the Select Committee in favour of discrimination The matter had not even been referred to in their official organ, the *South African Nursing Journal*, when the South African nurses were thus committed to apartheid At the last biennial conference of the association, a motion that the organisation should ask for equal pay for equal work for its members (African nurses earn just over half the salaries of white nurses) was voted down by a majority of white nurses Apparently, the South African Nursing Association does not recognise fully its duty to its non white members, and its present actions do not seem to be in line with the International *Code of Nursing Ethics*

The South African Nursing Council also gave evidence to the Select Committee,[4] recommending discrimination "You cannot have one standard for a highly developed race and the same for a lower developed race" The council asked that non European nurses should not be eligible for election to the Nursing Council, "a body which exercises disciplinary powers over thousands of women in this country (because) if such a nurse is able to sit in judgment on a European nurse who has transgressed you would wreck the nursing service in South Africa" To this, outsiders might reply that uniform standards would protect the status of white and black, and that there is no intrinsic reason why a white nurse should sit in judgment on a black but not vice versa

The effects of the Bill may be far-reaching for South Africa At present, the non European hospitals depend on non-European nurses With the limited professional opportunities offered them, many well educated and well principled young African women have been glad to train as nurses, welcoming the opportunity to serve their people and to gain status in their community The Amending Bill must reduce the standard and number of recruits, since non-Europeans in South Africa are naturally very sensitive to discrimination As it is, good nurses have been difficult enough to train within the present framework of the hospitals and the new Bill can only increase the difficulty The African nurse is an especially important link where most doctors (who are white) do not speak the language or share the cultural background of most patients (who are black) No reasonable standard of medical practice will be possible in the non-European hospitals without good nurses Indirectly, then, this Bill is a further and serious blow to the medical profession and its standards Doctors are resisting the imposition of double standards of training within their own ranks The case of the nurses seems to require the same response

INFLUENZA THREATENS

EPIDEMIC influenza is on the march again The epidemic in the Far East apparently started among refugees in Hong Kong in the middle of April Within a few weeks it has spread widely to other countries in Asia[5] and has now reached India, Japan, and Siam A laboratory report suggests that the virus is a new epidemic variant of influenza A, very different from previous epidemic varieties of this virus This finding has two implications first, it is unlikely that any population will have specific immunity to the new virus, secondly, vaccine made from virus of the previous epidemic variety will probably not give much protection against the new variant This country is unlikely to escape attack by this virus, but, since winter epidemics are the rule here, we may have a few months of respite If so, there should be an opportunity to prepare limited amounts of influenza vaccine with the new virus So far the death rate has been low, young children and old people seem to have been the hardest hit There is at present no reason to fear that the epidemic will increase in virulence, but a careful watch will undoubtedly be kept for deaths among young adults

MEDICAL CARE OF HUNGARIAN REFUGEES

THOMAS L. DORMANDY

CAPTAIN, R.A.M.C.

ON Saturday, Nov. 17, 1956, the first 50 Hungarian refugees arrived in this country and were taken to hostels in London. Twenty-six days later, when the Dakota *Sierra Whiskey* came through the low cloud and touched down at Blackbushe Airport, its passengers raised the total number of those that had been carried by air alone to 7524. It had been the biggest airlift ever to be organised from purely civilian sources; and its success made it necessary to open, at short notice, several reception and transit camps in the Aldershot area. On Nov. 23 Beaumont Barracks received 300 refugees; on Nov. 26 Talavera Barracks started to take in 1000; and, on the following day, Haig Lines Camp in Crookham received the first of 1200. More than 4000 refugees passed through these camps between mid-November and mid-February, when the last of the three, Haig Lines Camp, was closed. During these three months we were members of a team of general practitioners and officers of the Royal Army Medical Corps who were responsible for medical cover and, after the first rush, medical care. Medical centres were established in all camps, and sick-bays were equipped by the Cambridge Military Hospital and the British Red Cross Society at Talavera Barracks and Haig Lines Camp. Not counting those who came to us with mild headache, toothache, air sickness, cuts, bruises, broken spectacles and other minor complaints (and excluding routine medical examinations required for emigration and special employments) we saw 800 patients, more than two thirds of them during the first four weeks.

Emergencies on Arrival

Most of the refugees had already been through Austria—and almost all had passed through casualty-clearing stations on the Austro-Hungarian frontier—but some had only spent a few hours there before their onward flight to this country; and a few needed emergency treatment on landing.

A factory worker of 21 was in a crowd of demonstrators attacked with hand grenades on Oct. 24 in Gyor. Wounded in his left arm, chest, and face, he was taken to a local hospital where he received a blood transfusion and first-aid dressing. Because of the shortage of staff and equipment, no further treatment was possible. Ten days later, with 8 of his fellow patients, he set out for the Austrian frontier. The journey involved a walk of 15 miles through a forest and over ploughed fields, and six hours were spent in a rowing boat on Lake Ferto. (One of this group, a man of sixty, died in Austria from exposure; another, a child of 6, had to have bilateral below-knee amputations for frostbite.[1]) The patient, however, declared himself fit; and he was allowed to proceed direct to Linz and board a plane to this country. Eight hours later he reported at the medical centre in Aldershot, complaining of stabbing pain in his chest.

The left side of his chest was extensively scarred (with some superficial discharging wounds), wasted, and almost immobile. His left arm was also wasted and scarred; and shoulder movements were painful and restricted. He had several scars on his face and his left eye was inflamed. On questioning he admitted that his vision had become increasingly hazy in the left eye over the past six days and that he had a dull aching pain at the back of his eye. Radiographs at the Cambridge Hospital in Aldershot showed multiple metallic foreign bodies in the left chest wall and lung fields (but no fluid in the pleural space), and many in the left shoulder region. In the left eye there was a large shining pointed foreign body, with several splinters, and considerable retinal disturbance. This demanded priority treatment, and as soon as he had recovered from general exhaustion and his wounds were cleaned he was transferred to the Moorfields Eye Hospital in London. There, on Dec. 3, two foreign bodies were removed with the magnet. Though vitreous hæmorrhage obscured the view of the fundus, escape of subretinal fluid suggested a local retinal detachment; and at the follow-up visit four weeks later early retinitis proliferans was diagnosed. Back in the transit camp he received daily atropine and hydrocortisone drops in the medical centre. His vision in the left eye is at present exceedingly poor (counting fingers at 0·5 metre) and unlikely to improve. He gets an occasional sharp jab in his left chest on bending down; and he suffers from attacks of moderately severe, aching pain in his left shoulder after lifting.

Despite his disabilities, this patient was fortunate in many respects. Not only was he among the first arrivals, thus receiving the first wave of public sympathy, but he also escaped, through his illness, the inevitably demoralising effect of transit camps. However miserable he may have been at times in hospital—and one frequently found him in tears—nurses and fellow patients (mostly young soldiers evacuated from the Middle East) took turns teaching him English, shared with him presents from home, and made him part of their community. During his brief stay in the transit camp in February the difference between his outlook and that of many of his able-bodied fellow refugees, who had spent the preceding weeks (and the Christmas festivities) in the camp, was striking. He was anxious to start work, and employment was soon found for him as a nursing orderly in one of the London teaching hospitals. There, by all accounts, he is acquitting himself well.

Though minor degrees of frostbite were common, only 1 patient—a nun of 65—had to be referred for this to hospital. (She eventually had to have several gangrenous toes amputated.) Others who had to be sent straight to hospital included an exsanguinated woman with incomplete abortion, which had started during her wanderings on the Austro-Hungarian frontier; a young woman in status asthmaticus; 2 children with diarrhœa; an elderly bronchitic man with incipient heart failure; a case of active pulmonary tuberculosis who had had a second-stage thoracoplasty six weeks previously; and a mentally defective girl of 6 who had been so heavily sedated in Austria that she arrived in what appeared to be deep coma.

She was brought back to the camp two days later by her father, who a week earlier, had carried her across the frontier. She is a primary ament who had been treated unsuccessfully with large doses of glutamic acid for four years in Hungary. She cannot sit, stand, speak, or feed herself; she does not understand the Hungarian language; she has no control over her sphincters; and it is doubtful whether she recognises her parents. With her brother and sister she fell ill with whooping cough a few days later; and the whole family was isolated for ten days in a side ward of sick-bay. A fortnight later the family was presented with a cottage in an industrial town by newly won friends where the mother looks after the children. The father, a qualified engineer, earns a living as a factory worker.

Despite material shortages and difficulties (most of which were later overcome) the first few weeks saw such an extraordinary surge of human kindness that—hard as it is to recall its immediate effect even from the distance of a few months—they could not but leave a happy and exhilarating memory. Waiting for the first refugees to arrive, our first patient was in fact an R.A.M.C. corporal who had given up his long-planned holiday to help the Red Cross, and who, having worked to get the medical centre ready for the past thirty-six hours almost without a break, injured his hand chopping firewood for sick-bay. Gifts of expensive drugs, baby-food, and medical equipment had already begun to arrive from drug-houses, local pharmacists, hospitals, and anonymous donors; and voluntary workers soon came from all parts of the country to offer not only physical and material help but also a spirit of welcome.

---

The Language Barrier

There can be few aspects of refugee work where lack of a common language creates greater difficulties than medical care. Confronted, for several days and nights running, with coach-loads of exhausted, bewildered, pale, and often vomiting people of all ages and both sexes, most of whom complained of what sounded like (but one could not be sure that it was) nausea and abdominal pain, those of us who understood no Hungarian could not help feeling very uneasy labelling them, after a cursory glance, victims of air sickness. Mass relief always imposes a strain on doctors; and, unnoticed by themselves, they tend to concentrate more and more (in a hectic but profitless frenzy) on inessential trivialities. With the added language difficulty we were fortunate in missing only one major and obvious surgical emergency—a case of leaking ectopic pregnancy. She was diagnosed a few hours after admission to sick bay when an unexpected and distinguished non-medical visitor, who had asked to be conducted round, commented on her pallor.

There was, throughout the three months, a constant shortage of trained interpreters; and for this reason we had to refuse many offers of help from local practitioners. (It is unfortunate that—unlike food, clothing, or drugs—this most serious of all shortages, conceals itself. It is the probable explanation of explosive trouble reported from some camps in this and Continental countries where the camp authorities genuinely believed that all was well.) Untrained, incompetent, or merely tired and overworked interpreters can become a serious nuisance in medical work. Not only does this demand from them a high degree of accuracy and discretion, but medical topics also have an irresistible fascination to many lay minds. Most interpreters assigned to us were admirable in more than one way; but there were one or two who could not refrain from embellishing doctor's instructions with homely advice (painfully obvious from the length of time they took to translate a brief sentence) or from commenting on the merits (or otherwise) of all treatment prescribed; and, with a growing number of "difficult" patients, some—usually those least able to afford such extravagance—could not resist giving them, without our authority, "a piece of their mind". Occasional interpreters, much as one appreciated their intentions, often did a great deal of harm. In response to a nation-wide broadcast appeal more than 50 came during the first weekend to supplement the usual 3–4; and, wandering about the camps and comforting the refugees, but without any specific task, many succumbed to a Father Christmas attitude of vague promises and hopeful but inaccurate information. Dictionaries were exceedingly scarce; and most of the early improvised lists of "useful words and phrases" were a source of light entertainment rather than of enlightenment. Hungarian is quite unlike any other European language; and, though one soon realised that many *nems* and *semmis* in the medical history were a favourable prognostic sign, it was usually simpler to try to look comprehending than to try to comprehend.

On the other side of the language barrier hospital patients suffered much misery. Enfeebled by physical illness, lying in bed unoccupied in complete linguistic isolation, they could not guess what was about to befall them, nor could they be kept informed about their families and fellow refugees. Unfounded but appalling rumours which had already caused much nervous tension in the camps sparked off fits of hysteria when they reached the hospitals; and many patients discharged themselves against medical advice.

One night in December a three day post-appendicectomy patient was found by the driver of an Army truck, wandering about in her dressing gown two miles from hospital. She had misunderstood a piece of information given by a visitor to another patient, and had formed the impression that the camp, where she had left her young children in our charge, was to be moved to Scotland next morning. She was eventually pursuaded to return to hospital but discharged herself again three days later.

Hungarians, like most Continental people, take—by upbringing and by temperament—a far more active part in their illness than the average English patient. Detailed hospital reports which they carried around with them, and which gave diagnosis, the results of investigations, and often a far from favourable prognosis, showed how freely they had discussed their ailments with their doctors; and they held decided views about their own treatment. Lack of information thus imposed great mental strain on them, and delay in starting investigations and treatment for lack of interpreters (especially with gynæcological patients) prolonged their anguish. Despite the familiar difficulties of treating patients with even minor illnesses in barracks, steadfast refusal of parents to part with their children often made this an unwelcome necessity; and in two cases of infectious fevers one of the parents had to be admitted to the isolation hospital with their sick child. Relatives and visitors from the camps were otherwise taken on daily "milk rounds" of the local hospitals by special bus; and progress reports about Hungarian inpatients were received at the camp medical centres every morning and passed on to relatives who called later in the day.

The Seriously Ill

The standard of physical fitness amongst the refugees was generally high; but it was equally remarkable how many seriously ill patients had embarked on the journey. A whole group of young men and women with advanced rheumatic heart disease had escaped because they had felt—rightly perhaps—that conditions in Hungary did not allow adequate treatment of their illness, and because they had read (or heard on the radio) that it could be cured by surgical means in this country and in America. Most of them had mitral incompetence in addition to mitral stenosis; one had an acute relapse in the camp, with joint swelling and pericardial effusion, and had to be sent to hospital; and all the others were put on prophylactic sulphonamides.

Liver disease was another illness which was surprisingly common and often difficult to manage under camp conditions.

Lying in a wet ditch for several hours on the Austro-Hungarian frontier, a woman of 32 caught a chill. On arrival in Aldershot she complained of general malaise, shivering, nausea, constipation, and a dragging sensation rather than pain in her abdomen. She gave a history of acute hepatitis in 1951 for which she had had two weeks in hospital; but, though she had been on a waiting list for two years she had not received any inpatient treatment since then. She was persuaded with some difficulty to go to hospital, where investigations showed gross impairment of liver function. Anxious to return to her fiancé in the camp she was discharged at her own insistence after ten days. In the transit camp a special diet was arranged for her; and in the medical centre she received extra fruit, biscuits, and compound vitamin tablets. She remained well except for amenorrhœa and occasional abdominal discomfort. Both she and her fiancé had left Hungary hoping to emigrate to Canada where a job is waiting for him. They are now expecting to be called for a medical examination to be certified fit for emigration.

Most other chronic illnesses were represented among the refugees—duodenal ulcer, pulmonary tuberculosis, bronchiectasis, ulcerative colitis, thyrotoxicosis, and diabetes mellitus. We looked after several cases of gunshot wounds, a 40-year-old man with abdominal carcinomatosis, a 30 year-old gipsy woman with advanced Cushing's syndrome, and a woman of 26 who—after an attack of mumps encephalitis at the age of 10—started to put on weight and now weighed 23 st. Our most unusual cases were a married couple with diabetes insipidus.

The husband was the last in a queue of new arrivals, most of whom had come to the medical centre for tablets against headache, toothache, constipation, sore throat, dysmenorrhœa, or air sickness. He came to ask for a fresh supply of posterior pituitary extract. He had run out of tablets in Hungary ten days before, and since then he had been drinking over 14 litres of fluids daily and passing a corresponding amount of urine. He had no other complaints. He was 35, his home had been on the Hungarian-Rumanian frontier, and he professed to be an "importer and exporter of various goods." In June, 1956, he had escaped capture by frontier guards by falling into a well, and on his way home next morning had noticed unusual thirst and the need to pass urine frequently. A week later his doctor diagnosed "pituitary insufficiency due to shock", and on tablets of posterior pituitary extract his fluid intake fell to about 2½ litres daily. Four months later the outbreak of the Hungarian revolution caught him ill with gastritis in Budapest, and he volunteered the information that during three days spent vomiting and in semi-starvation in an air raid shelter his symptoms improved spontaneously.[2]

He drank 3 litres of fruit juice during our first interview and later he passed 3½ litres of clear urine. Next morning we provided him with posterior pituitary snuff and an insufflator which was an unqualified success. The organic nature of his symptoms was later confirmed in hospital by urine concentration tests and the intravenous hypertonic-saline test[3]—and diabetes mellitus and renal disease were excluded—but the underlying lesion was not easy to determine. There was no positive family history, his past history revealed no illness which could be incriminated, and clinical examination, and serological and radiological investigations were negative. It thus seemed reasonable to ascribe his illness to the traumatic episode eight months previously, despite several atypical features.[4–6]

He remained well-controlled on posterior pituitary snuff, which he preferred to intramuscular vasopressin tannate, but he was worried about his wife who had left Hungary a few days after him and who had had a nervous breakdown in Austria. After a somewhat laborious process of tracing her we learned from her Austrian doctors that she had already recovered from her anxiety symptoms but that she was now being investigated for severe diabetes insipidus. A further exchange of telegrams followed and she finally arrived, her polydypsia perfectly controlled on unlabelled phenobarbitone gr ½ three times daily.

Mental Illness

Diagnosis and treatment of psychiatric disorders depends, more than that of any other type of illness, on the spoken word, and they are perhaps least suitable for management in transit camps where a great deal of undesirable publicity can never be avoided. Chronic psychotics are probably few among the refugees (we only saw one recently treated case of schizophrenia, though several others were seen at a specialist hospital in London[7]), but minor psychiatric disorders may yet prove a bigger and more formidable problem than physical illness. The emotionally unstable, the perpetual drifters, the chronic failures—in whose catastrophic lives revolution and escape were but passing episodes—often reacted violently to the growing stresses of refugee life. Friends of nobody and their own worst enemies, it was not only hard to visualise them settling down to normal life, but, unable to make themselves understood, they ran a very real danger of being misdiagnosed as cases of major psychosis certified, and taken to mental hospitals. (Cut off from all contact with doctors, nurses, and fellow patients, even a brief sojourn there could only have a disastrous effect on them.) Hardly less gloomy appeared the future of the dull and the high-grade mental defectives. Most of those have been able to lead a normal, if limited, existence in their own milieu, but, despite popular good will and full employment, it was already becoming clear that many will be incapable of coping with their accustomed work in addition to the burden of learning a foreign language and adapting themselves to a foreign way of life. The future of young children was often our most immediate concern.

The younger of two usually quiet and well behaved brothers, a boy of 10, caused great stir amongst the other children when he collapsed and had a grossly histrionic fit. From the parents we gathered that both boys had been "difficult" for some months past: the younger had already had fits of naughtiness, whereas the older had become excessively shy and had recently started to wet his bed. The father appeared nervous, secretive, and mistrustful: the mother, who had already undergone neuro psychiatric treatment in Hungary, roused all other inhabitants of her barracks two nights later when she had a fainting and screaming fit herself. This was followed by excruciating headache and transient blindness. We referred the whole family to the Maudsley Hospital in London for psychiatric interview by a Hungarian speaking doctor. He reported that "both boys appeared intelligent and their symptoms are reactive to maternal mishandling. The mother has had considerable difficulties in her personal relationships and the marriage had been under stress for many years. . . . The tragic events of the last few months, their present unsettled circumstances, and uncertain prospects are further endangering her already precarious adjustment. She now shows a tendency to translate her difficulties into somatic terms. I couldn't find anything wrong with the father . . . but he says that he is heading for a nervous breakdown if his wife continues to behave as she has done in recent months."

The family was eventually, and not without difficulty from both parents, transferred to a London hostel so that the mother and children should be able to attend for psychiatric outpatient treatment. There they soon got into further trouble. The father—a morose and unpopular man—was said by some of his more vocal fellow refugees to have been in the secret police in Hungary and even now to be travelling to and from Hungary regularly to report on refugees in England. (This was a not uncommon, often genuinely held, but usually quite ill founded accusation. In this case, we could easily have disproved it, since he had spent the days of his alleged journeys to Hungary in the camp near Aldershot.) The mother drifted into loose company, refused for several weeks to see the psychiatrist, and aroused the bitter resentment of the more sober group of refugees. The father then abruptly returned to Hungary, leaving his wife and two sons—who are still causing grave anxiety to the hostel authorities—to fend for themselves.

Most hysterical manifestations in the camp—rare at first, but gradually becoming commoner—were of this crudely transparent type, conforming more to the picture of the disease familiar from popular fiction (and to Charcot's classical case-histories) than to the more subtle and complicated forms seen in medical practice in Western countries today.

Welfare

Individual and communal welfare—as also the day-to-day administration of the camp—was in the very capable hands of the Hampshire branch of the British Red Cross. The 54 pregnant women whom we saw and registered at the medical centre received extra food, vitamins, and clothing, and most of them were examined in the antenatal clinic of the Louise Margaret Hospital in Aldershot. (The first refugee child was born there on Dec. 14, 1956.) Great efforts were also made by the camp authorities to find for expectant mothers some more suitable accommodation than Army barracks, where they could receive continuous antenatal and postnatal care This unfortunately proved difficult although cubicles were provided, and there were communal heating and washing facilities, privacy for individual families was inadequate in most camps and hostels

Like expectant mothers, babies were supervised at the medical centre Most mothers looked after them extremely well—if in a different manner from English parents—and neglect and cruelty were unknown Older children, however, reflected with uncanny fidelity—usually by how they behaved rather than by what they said—the prevailing moods, preoccupations, and tensions in the camp For a week or two in January, when a rumour circulated that the whole camp would be shipped to Northern Ireland, there was an "epidemic" of children going off their food, and mother after mother came to the medical centre, exasperated (both persuasion and chastisement having failed) and insisting that their children would simply fade away We reassured them as best we could, and we gave the children tonics and vitamin tablets "to keep them going" but real improvement only came when the Red Cross and school authorities arranged for all children to attend the local schools regularly They were collected and taken there by special bus every day, and almost all seemed greatly to enjoy the experience

Perhaps the most difficult, if least medical, aspect of welfare—the moral welfare of young people—could hardly be tackled properly in a transit camp The rootless and the restless not only formed a comparatively large proportion of the camp population (especially as more and more of the others found work outside), but in the camp atmosphere of enforced idleness, uncertainty, and lack of all personal responsibility they also influenced many young waverers The generally agreed policy was one of minimal interference with the private lives and living arrangements of the camp population, but one could not escape a feeling of profound misgiving when girls of 15 and 16, some of whom had left behind a stable and happy family background, came to the medical centre "to have something done" about their unwanted early pregnancies (Birth control was practically unknown among the refugees and, by all accounts, abortion had been semi legalised in Hungary during the past few years)

Problem Patients

One of us, who speaks Hungarian, had to deal with a growing number of "problem" patients, many of whom were brought to us from other parts of the country by their hosts or employers

A farmer motored up from Devon with a young Hungarian—one of four whom he had taken away from the camp soon after their arrival and to whom he had given a cottage and work on his farm The patient had apparently been quite happy during the first week in his new job, but since then he had been complaining of a variety of digestive symptoms These were ascribed by his doctor—who, according to his letter, could neither make sense of what the patient told him, nor convey to him his own instructions—to peptic ulcer, gastritis, or a grumbling appendix The patient's main complaint was ill localised abdominal pain which gave him no respite and which was unaffected by food, the doctor's medicine, or posture He also complained of much nausea but no vomiting, his bowels were regular, and his appetite was fair He mentioned giddy spells on bending down, and a 'feverish' feeling at night, but he slept well, and he had lost no weight Clinical examination was negative, except for diffuse abdominal tenderness and a spastic sigmoid colon

The patient was emphatic about liking his new work and his employers and he seemed distressed at the thought that he might be taken for the Hungarian equivalent of a 'skiver" On closer questioning, however, he was resentful on several counts First, he received £2 less in weekly wages than the English farm workers (This, because of the language difficulty, he considered not unreasonable, but "why was he not told before?") Second, his wife (to whom he was not legally married) had been asked to do housework without extra pay Third, he felt that he ought to have been investigated in hospital from the onset of his troubles In a more general vein, he was critical of most features of English life, including the weather

In Hungary, he had been a miner for the past six months, but, at 29, he had already travelled in four continents At 17 he ran away from home, joined the Hungarian army, and was taken prisoner by the Russians After several unsuccessful attempts he escaped from a P O W camp to China, only to be handed back to the Russians six months later by the Chinese Communist army From another P O W camp in the Ukraine, however, he eventually made his way back to Hungary, just in time to attach himself to the German army in its retreat to Austria In 1945, from a displaced persons' camp in the French zone, he enlisted into the French Foreign Legion, and he fought in Madagascar and Indo China for six years In 1952, he was shipped back to Germany, deserted, and, by way of Italy and Yugoslavia, returned to Hungary There he married his first wife, by whom he had a child, and he held a succession of jobs interrupted by several prison sentences and a brief spell as an army officer Although he took no active part in the revolution, he now "just couldn't stick the regime" any longer

Even in ordinary practice such cases are troublesome and medically unrewarding, but here there were additional difficulties Normally when advising patients against expensive and time consuming hospital investigations, one does so with the comforting thought at the back of one's mind that they are left with an almost unlimited choice of alternative doctors whose counsel they can seek This patient, on the other hand, would not get another chance for a long time even to voice his discontent Similarly, even the slight benefit of superficial psychotherapy would be denied to him as soon as he had left our consulting-room One also feared that discussion with his employer of his grievances—some of which may not have been entirely unjustified—might cause ill feeling and one was far more aware than many of the refugees themselves how much their future welfare depended on public good will Finally, one's loyalty to the individual patient was strongly assailed by the knowledge that there were many other young men in the camp who, hard working and dependable, would have been anxious to take on his job and would have done far better in his place However, we reassured the patient about his symptoms, we had a frank talk with his employer (who proved far more understanding than we had expected), and we wrote a detailed case history to the doctor

We saw the patient again three days later when he came for a routine medical check with a group of young men who had volunteered for the mines He looked cheerful and ("thanks to your tablets, doctor") he felt perfectly fit, and there was, of course, no medical reason against his returning to his old occupation Later, however, we got in touch with his previous employer who told us that not only had the patient left him at a most awkward time and without giving notice, but that he had also persuaded three of his fellow refugees to do the same, that his doctor had already gone to a great deal of trouble in arranging hospital investigations for him, and that in no circumstances would he or any of his friends employ Hungarians again

Not so much the patient as his employer's reaction was in many ways typical it reflected a dishearteningly widespread misconception of the refugee problem Events in Hungary had stirred most people's imagination in this country, but during their impressive display of human solidarity towards the victims few faced the fact that the migration of more than 150,000 people had been a tragic side effect, not part, of the political drama Thousands of families were not driven out of Hungary either by famine, fear, or force of arms, nor, of course, did they simply try to escape physical discomfort The forces which uprooted them were probably as irrational and abnormal by ordinary peace time standards as the forces which, in war, drive gentle and law abiding citizens into action Few soldiers in battle think in ideological or even national terms and it is doubtful if more than a handful of refugees did so before setting out on their flight The outbreak of the revolution caused not only a sudden and complete upheaval of their country's social and political order, it also upset all conventions of behaviour and the open Western frontier, sealed for so long, was certainly a powerful force of attraction even to the least adventurous

Most refugees arrived in the West still in this unsettled state of mind, and only there, and only gradually, were they to realise that they had exchanged the hardships and insecurities of a political regime for the equally crippling, if more transient, hardships and insecurities of life in a foreign country Many had left young children and sick parents behind without, it seems, pausing to consider that the parting may be for good and in the intoxicating atmosphere of the revolution many must have felt that political frontiers would soon be reduced in importance to derelict level-crossings

After their escape other unfavourable psychological influences were bound to make themselves felt In a heterogenous, ill organised, and often disillusioned crowd, comradeship, leadership, and respect for those left behind —the familiar foundations for front-line morale—were lacking; and, on the other hand, the equally familiar and most potent cause of its decline, a feeling of "not being kept in the picture," was present from the start (This was only partly imposed by the language barrier Too often, especially when urgent group movements were necessary, grossly inaccurate information was used as a short cut to gaining the cooperation of the refugees Even force is preferable to such a policy which only creates a vicious circle of disappointment, mistrust, passive resistance, and even more glamorous and unsound promises) Many refugees became acutely aware—and some were almost obsessed by the thought—that in the eyes of their hosts any refugee must appear "pretty much like the next one" but it was usually the highly sensitive ones—those who protested their individuality most—who found it least easy, when the time came, to abandon the security afforded by being part of a crowd It is hardly surprising that many refugees—even those emotionally most stable and intellectually sometimes brilliant—passed through a phase which no more reflected their normal selves than it fitted into the normal life of the country which gave them refuge

It cannot be too strongly emphasised that this is not a political problem and it is doubtful whether physical measures alone, modelled on disaster relief at home, can solve it They may be needed, but to be effective they must be applied with a clarity of judgment which can only come from a thorough understanding of the underlying psychological conflicts and difficulties Individual charity too has an immensely useful part to play, but it must guard against drawing too sharp a distinction between the "deserving" and the "undeserving poor," and it must be given not only with sympathy and patience but also with some degree of detachment However generous, it can never be a short cut to the resettlement of many thousands of homeless people of varying intelligence, background, and physical fitness This is a task which requires highly trained teams of social, psychiatric, educational, and medical workers There is no doubt that the trouble and expense of recruiting such teams, however great, would prove a sound investment both materially and in terms of human happiness

Only to a few of those who have helped us—sisters nurses, interpreters civilian and R A M C voluntary workers, and both English and Hungarian medical colleagues—can we express our thanks by name and for the work done by staff and members of the British Red Cross Society we can but record our admiration We should like, however, to thank especially Miss E Balfour O B E, the Red Cross Camp commandant, and Miss E Pilkington, deputy commandant for their unfailing coöperation, and to Colonel A. N Odbert, O B E, A D M S Aldershot District, we should like to express our gratitude for his guidance and interest both in our work and in the preparation of this article We were greatly helped by the patience and ingenuity in overcoming the language difficulty of the medical, nursing, and administrative staff of the Cambridge Military and Louise Margaret Military Families' Hospital in Aldershot, and the Aldershot General, Northfield Isolation, and Farnham Hospitals We also wish to thank Colonel H C Benson, commandant, R.A M C Depot and Training Establishment, Crookham, and his staff, for manifold assistance, Capt B Pritchard, R A D C, for looking after our dental patients, Dr J Craig Lindsay, medical officer of health for Aldershot, for valuable support, and Dr A Mezey, senior registrar at the Maudsley Hospital, London, for devoting so much thought and time to some of our most difficult cases

We are grateful to the Director General, Army Medical Services, for permission to publish

MENTAL ILLNESS AND THE LAW

Recommendations of the Royal Commission

TIMES change, and the law must change to keep in tune with them This is the burden of the Royal Commission's unanimous report[1] The objects of the law are to give the patient the best care, to protect the public, and to prevent the abuse of compulsory powers, but "advances in medical knowledge, new methods of treatment and the development of new organs of government and new social services have naturally demanded changes in the medical and administrative methods by which these objects are pursued" The present laws were passed at a time when it was assumed that all mentally disordered patients must remain in custody during treatment, and it will now be necessary to repeal the Lunacy and Mental Treatment Acts and the Mental Deficiency Acts A new Act will be needed to take their place, and certain other statutes will have to be amended—e g, those concerning marriage, divorce, and property of mentally disordered persons and sexual offences against them, Broadmoor Institution, and liability to National Service The Board of Control will be abolished

The new recommendations of the commission are summarised below

The Patients

For legal and administrative purposes, three main groups of patients should be recognised

(1) Mentally ill patients, including the aged with mental infirmity The term 'person of unsound mind" would no longer be used

(2) Psychopathic patients The commission use the term "psychopathic personality" in a wide sense to include any type of aggressive or inadequate personality which is recognised medically as a pathological condition but do not render the patient incapable of leading an independent life The term includes all such patients now classified as feeble minded or moral defectives needing care

(3) Patients of severely subnormal personality—i e, those incapable of leading an independent life The term would include all those now classed as idiots and imbeciles, and some now classed as feeble minded The terms "idiot," 'imbecile," and "defective" would no longer be used

'The administrative distinction between mental illness and mental deficiency has a sound practical basis, but the rigidity with which it has been enforced through two separate legal codes has had some unfortunate results The grouping of all types of defectives together has led to the supposition that they must be a more homogenous group of patients than they really are"

Accordingly, there should be no rigid legal designation of a hospital catering for only one of these groups, the extent of specialisation would be a matter for medical and administrative arrangement Most of the mentally ill do not need to be admitted to hospital as inpatients, but for those requiring inpatient care new arrangements are proposed A single Act would define the procedure of admission to hospital of mentally disordered patients of all three groups

---

[1] Royal Commission on the Law Relating to Mental Illness and Mental Deficiency 1954–57 Report Cmd 169 Pp 324 H M Stationery Office 10s 6d

Admission for Care

At present a patient can be admitted to a mental hospital only (1) as a voluntary patient (i e, he must be well enough to sign an application form), or (2) on certification, which may carry a certain social or moral stigma, because many people wrongly think that "certification" implies that the patient is permanently deranged or dangerous The term should be dropped Instead, "all forms of hospital and community care should be available in future to patients who are content to receive them" The voluntary-admission procedure should be abandoned Admissions should be arranged in the same way as admissions to general hospitals, with no statutory fixed notice of intention to leave, patients should be assumed to be content to be admitted unless they positively object This should apply to patients in all groups

> "Every effort should be made to persuade patients and their relatives to agree to care without compulsion But if such efforts fail, doctors and others should not be too hesitant to use the compulsory powers which the law provides, when this seems the only way of giving a patient treatment or training which he badly needs or when such powers are necessary for the protection of others"

Many of these will need admission to hospital, but some are better placed under the guardianship of the community, and to them the same principles apply Local health authorities should have a duty to act as guardians where necessary

The special position of psychopathic patients is considered They are distinguished from normal citizens not by their loss of reason or lack of intelligence but by their behaviour, and the special wide powers of compulsion allowed by the present law is not now justifiable, though there are grounds for providing compulsory training for the young, and for compelling psychopathic patients of any age to enter hospital for only short periods Unless, then, he has broken the criminal law, a psychopathic patient should be liable to compulsory admission (where necessary) if under the age of 21 at the time of admission, but must be discharged by the age of 25 (unless he has become liable to compulsion for other reasons) At any age psychopathic patients (as well as mentally ill and severely subnormal patients) should be liable to compulsory admission, for observation for periods not exceeding twenty eight days, or for care after criminal conviction when the court thinks it necessary and the hospital is willing to provide it Criteria for distinguishing psychopathic and severely subnormal patients are outlined in the report, but detailed definitions should not be written into the law The authorities should not be reluctant to bring a criminal charge against a psychopathic patient, for he is responsible in the eyes of the law, and a conviction may be the only way to ensure that he is treated

No formal designation is necessary by the Minister of Health of hospitals to which "compulsory powers" apply, it should be for the hospital boards and committees to decide which hospitals have powers of detention No hospital should be obliged to admit a patient for whom it cannot provide suitable care Patients compulsorily admitted should have the same status as others No letter written by any patient should be censored except at the request of the addressee, but hospital authorities should be empowered to withhold from the patient any incoming letter which it might harm him to receive There should be no statutory notification of a patient's discharge, but the relatives and general practitioner should be notified informally, as well as the local health authority if it is to provide aftercare

In sum, the main procedures for admitting a patient to compulsory care are

(1) Except in emergency, there should be two medical recommendations—preferably one by a doctor experienced in mental disorders (usually on the staff of the admitting hospital) and one by a doctor who already knows the patient In emergency, one recommendation would suffice, but the second must be added within seventy-two hours (twenty-eight days in the case of guardianship) (The present reference to a justice of the peace—often merely a formality—should cease, for it links treatment of mental disorder with the authorities responsible for the punishment of crime)

After twenty-eight days, a patient compulsorily admitted to hospital as an emergency would have to agree to continue in care (if this was necessary), otherwise a fresh application would have to be made with medical recommendations and a more precise diagnosis (Psychopathic patients over the age of 21 could not thus be detained unless this was authorised by a court after criminal proceedings)

An application for compulsory admission to hospital or guardianship, with two supporting medical recommendations, would authorise detention for up to a year Before the end of this year, if the patient was still detained, the medical superintendent or medical officer of health should review his case, and (if compulsory care was still thought necessary) sign a recommendation of further detention, with reasons, this would be reviewed by the hospital management committee or local health authority Similar recommendations would be made at increasing intervals where necessary

(2) The recommendations for admission must contain either a diagnosis of mental illness, of psychopathic personality, or of severely subnormal personality, and a recommendation for hospital or community care, or a diagnosis of mental disorder and a recommendation for up to twenty-eight days' observation in hospital In the first case, full explanation must be given of the need for hospital care or guardianship and of the necessity for compulsion

(3) Application by a relative or mental welfare officer, supported by medical recommendation, should authorise the detention, without reference to a magistrate

(4) Powers of discharge would be held by the patient's nearest relative (unless a certificate barred this because the patient was dangerous), a responsible doctor, any three members of the governing authority, and on special occasions, mental health review tribunals The tribunals would be appointed on a regional basis, by the Lord Chancellor, and include medical and legal members patients or relatives would be able to appeal to them against detention in certain circumstances

(5) Where an appeal is made against the decision of the tribunal, the Minister of Health (represented by a staff of part-time medical and non-medical officers) should scrutinise the documents in the case, and if necessary make further inquiries, with the power to discharge patients against the tribunal's decision This staff must be ready to visit any patient who asks to be visited

(6) Admission and renewal documents should be scrutinised by the hospital or local health authority staff—not centrally as at present Members of hospital management committees should visit patients regularly, and patients should be allowed private interviews

Other procedures would apply when it was necessary to override the wishes of the patient's nearest relative

(7) The local health authority should have a duty to provide special training for children for whom an ordinary school is inappropriate Hospital or community care would be appropriate in some cases under the Children and Young Persons Act

(8) In other cases where the nearest relative unreasonably opposes the provision of care an application (with

medical evidence) should be made to a magistrate's court for some other person to be granted the relative's power to apply for admission and discharge. The relative would have the right of appeal to quarter sessions and would retain the right to apply for discharge and to ask for a review by a mental-health tribunal.

(9) In emergencies, if another relative or the mental-welfare officer was so convinced that the nearest relative was acting unreasonably that he was prepared to apply to a magistrate's court for his wishes to be set aside, the main emergency procedure (as in (1) above) could be used, with a statement that the nearest relative was acting unreasonably.

Special considerations apply to court cases and transfers from prisons or approved schools.

(10) Where persons brought before a court were said to be mentally disordered, a medical report should be given by two doctors of standing similar to those who recommend compulsory admission. If the report agreed that the person was mentally disordered it should include advice as to the best way of dealing with him, and (if care was recommended) a statement of acceptance by the doctor who would be responsible for treatment or training. For some patients penal methods would be more suitable than medical. If the court was satisfied that penal measures alone were insufficient, and that care was necessary, care should be provided with the knowledge of the court but without its order.

(11) If a court of quarter sessions or assize was satisfied that immediate release of a patient would lead to further offences, it should direct that the patient should not be set at large without the Home Secretary's consent, and if the hospital or local authority wished to discharge the patient before the Home Secretary wished him to be released, other arrangements for his detention should be made.

(12) When admission followed court proceedings, the nearest relative should have power to apply for discharge but not to order it. In the case of an adult psychopathic patient, the need for compulsion should be reviewed annually by the authority caring for him.

(13) The Home Secretary should be able to authorise the transfer to care of persons, in prisons or approved schools, who are found to be mentally disorderd. The mechanism would be similar to that for court cases.

Private hospitals and nursing-homes, whether run for charity or for profit, receive special consideration.

(14) No member of the staff should be able to make application for compulsory admission, and both medical recommendations should be from outside doctors. Powers of visit and discharge should be held by members of the registering authority, and they must be allowed to inspect documents authorising detention.

Provision is also made for private persons (rather than local authorities) to become guardians, if authorised by a local authority or court, or after court proceedings.

Hospital and Local Authority

A new definition is made of the functions of the hospitals and local authorities.

> "There is increasing medical emphasis on forms of treatment and training and social services which can be given without bringing patients into hospital as inpatients or which make it possible to discharge them from hospital sooner than was usual in the past. It is not now generally considered to be in the best interests of patients who are fit to live in the general community that they should be in large or remote institutions such as the present mental and mental deficiency hospitals. Nor is it a proper function of the hospital authorities to provide residential accommodation for patients who do not require hospital or specialist services nor to provide other care for patients who have left hospital apart from necessary medical follow up or outpatient services. The division of functions between the hospitals, local authorities and other official bodies should be broadly the same in relation to mentally disordered patients as in relation to others."

The hospitals should provide inpatient and outpatient services for those needing specialist medical treatment or continuous nursing, including the subnormal who cannot be nursed at home, and inpatient training for subnormal and psychopathic patients where this necessitates psychiatric supervision. The local authorities should be responsible for preventive services and for all types of community care for those who do not, or who no longer, need inpatient care, including day or residential training-centres, residential accommodation in private homes or hostels, especially for the old, and general social help and advice. They should provide aftercare as long as it is necessary, without needing compulsory powers.

The local health-authority services should thus be much expanded, and should continue to include the provision of special training centres, though local education authorities should be allowed to cater for more children in the lower ranges of ability where possible. Some buildings now used by mental deficiency institutions might suitably be transferred to local authorities for these purposes; for the rest, Exchequer help is recommended.

Diagnostic clinics should be set up, on the lines of child-guidance clinics and perhaps based on them, but dealing with adults. They would be particularly useful for the diagnosis and assessment of psychopathic and severely subnormal patients, for clinical conferences between hospital and local-authority staffs on the best course in individual cases, and for advising the courts in cases where there is a possibility of mental disorder.

The provision of some community services by the local authority is at present a duty only for defectives and the aged infirm: it should be a duty for all mentally disordered patients.

Administration

The central supervision of all health and welfare services is now a function of the Minister of Health, and, in line with the integration in them of the mental-health services, the Board of Control would cease to exist, for it would have no function. This was suggested by the board itself. The functions of visitors appointed by justices would be taken over by the mental health tribunals and the local authorities.

The Minister should have powers of control over the standards of residential homes provided by the local authorities, while the local authorities should take responsibility for registering private institutions for mentally disordered patients, and for the oversight of patients in private houses: this would need new legislation.

The Minister of Health should consider whether the three State institutions should be brought within the administrative system of the National Health Service, or be managed by one or more special committees. In either case the committee(s) should include members who could often visit the hospitals as in any other mental hospital. The Minister should also review the arrangements for central collection of statistics.

Perhaps the kernel of the report is contained in these sentences:

> We consider it essential that the mental health services should continue to be an integral part of the present national health and welfare services. There is no longer any need for special mental health legislation to provide authority for the provision of public hospital or community services or the registration or approval of private establishments.

The report includes a tribute to the work of the Board of Control since 1913, and ends with an expression of thanks to Miss H. M. Hedley, the commission's secretary.

The members of the commission were:

Lord PERCY OF NEWCASTLE (chairman), Sir CECIL OAKES, Sir RUSSELL BRAIN, P.R.C.P., Dr T. P. REES, Lady ADRIAN, Mr C. BARTLETT, Mrs E. M. BRADDOCK, M.P., Sir HARRY HYLTON-FOSTER, Mr R. M. JACKSON, Dr D. H. H. THOMAS, and Dr J. GREENWOOD WILSON. Mr J. E. S. SIMON, Q.C., M.P., replaced Sir Harry Hylton Foster on his resignation.

GENERAL MEDICAL COUNCIL

SESSION MAY 28–29

NEW *Recommendations as to the Medical Curriculum*, designed to give greater discretion to licensing bodies and medical schools, were approved by the council last week. The number of subjects on which students must be examined has been reduced from 15 to 10, but the length of the curriculum is not altered. "A lighter and more flexible curriculum is the first essential," states the introduction to the *Recommendations*. "If a reduction in duration is to follow, a second operation will be required."

REPORT OF CURRICULUM COMMITTEE

The committee's introduction said that the most important criticism of the *Recommendations* of 1947 was that they left insufficient scope for initiative and experiment on the part of the licensing bodies and schools.

Until recently it was possible to proceed to independent practice immediately after qualification, and the council's *Recommendations*—and indeed medical education in general—had therefore emphasised vocational training and experience. This emphasis, together with the advance of knowledge and increase in specialisation, had caused the curriculum to become congested, and students had tended to concentrate unduly on memorising factual data. "The council feel no doubt that an effort should be made to reduce the congestion," the report continued, "and this has been their primary purpose in modifying the form and content of their *Recommendations*." In contrast to those of ten years ago, the present *Recommendations* indicated the minimum length of the whole period of professional study but refrained from saying how long should be allotted to particular subjects or the sequence in which they should be taught.

Corresponding changes had been made in the *Recommendations as to Professional Examinations*. While the council specified 10 subjects in which candidates should be examined they did not specify subjects in which separate examinations should be held.

Some licensing bodies and schools had suggested that the duration of the medical curriculum should be reduced. But the council felt that the primary task at the present time was to find means of reducing the congestion in the curriculum—to instruct less and to educate more. If it were simultaneously to be shortened, the principal object of the proposed reform would be thwarted. The council could say to licensing bodies and schools: "We are lightening the *Recommendations*, and we hope that in future your courses need no longer be overloaded"; but they could not reasonably say at the same time: "We ask you also to shorten your courses."

In professional education it was desirable that "inter-departmental teaching should be encouraged throughout the whole period of professional study. The memorising and reproduction of factual data should not be allowed to interfere with the primary need for fostering the critical study of principles and the development of independent thought." To ensure that students are fit to continue the work which they have undertaken, "there should be an adequate test or examination in normal structure and function not more than two academic years after the student has entered on the period of professional education."

Instruction in medicine and surgery should include clinical clerkships in medicine, surgery, and pædiatrics for not less than fifteen months in the aggregate. "It is desirable that for a part of the time of clinical clerkship the student should reside in hospital or conveniently nearby"; and "the student should be given opportunities to learn something of the work of the general practitioner." Instruction in psychological medicine should be carried out mainly in a psychiatric department, where neuroses and psychoneuroses could be studied. Not less than two months of the time devoted to clinical instruction in midwifery should be spent by the student in residence either in a maternity hospital or in a hostel attached to a maternity hospital or in the maternity wards of a general hospital, during which period the student should personally conduct an adequate number of cases of labour. Instruction in pathology and bacteriology should be given in association with clinical studies.

Candidates should be examined in anatomy, physiology, biochemistry, medicine, surgery, midwifery and gynæcology, pathology, bacteriology, and pharmacology. Examinations in the subjects included under medicine (child health and pædiatrics, social and preventive medicine, and psychological medicine), and in the various specialties in medicine and surgery, may be separate examinations or may form part of examinations in medicine and surgery. The final or qualifying examination is to be in medicine, surgery, and midwifery and gynæcology. "Examiners should be empowered to take into account the duly attested records of the candidate throughout his course of study."

DISCUSSION

In introducing the report Sir **DAVID CAMPBELL** spoke of a spirit of adventure now abroad in medical education—a desire to experiment. As regards training in the basic sciences, he rejected the suggestion that these are not cultural subjects. He thought it desirable that such training should take place in university or medical schools, "but unfortunately we have got to face the situation that a great many receive the training in schools."

Prof. H. R. **DEAN** (Cambridge) said he had been struck by the immense time taken in schools in reaching the standard in these subjects—two or three years compared with the single year spent on them in a medical school. This had unfortunate results in that it shortened the period of general education.

Turning to professional education, Sir **DAVID** pointed out that "adequate experience of dissection" was now laid down, as compared with the 1947 recommendation that the whole of the human body should be dissected. "We leave it to the medical schools," he said, "to interpret the word 'adequate' in this connection." In regard to midwifery it was impossible to lay down a definite number of cases of labour to be conducted. In view of the claims made for drugs, and the visits received by practitioners from "those itinerant professors of therapeutics, the representatives of pharmaceutical firms," he thought it highly desirable that the student should have adequate instruction in pharmacology, *including* the principles governing the design and interpretation of clinical trials.

Prof. J. H. F. **BROTHERSTON** (Edinburgh) welcomed the form of the *Recommendations*, which he described as "an enabling statute which gives freedom to experiment." He wondered whether it was still necessary to specify the period to be spent in residence during clinical instruction in midwifery. Edinburgh University also saw with some regret the dropping of specific reference to therapeutics. They felt that therapeutics had played an important part in the training of students and there was a place for it, perhaps alongside pharmacology.

Dr. J. G. **MCCRIE** (Sheffield) also appreciated the freedom of the *Recommendations*, but he agreed with Dr. Brotherston about the midwifery period. Similarly he thought that there was perhaps no reason to specify a particular period of time—fifteen months—for the clinical clerkships in medicine, surgery, and pædiatrics.

Mr. **VICTOR LACK** (Royal College of Obstetricians and Gynæcologists) said that they had fought for a long time to get a decent period of residence, so that students could see the work of the department of obstetrics, which after all took place mostly at night. If the council made a loophole, the standards in that branch of the student's education would be endangered

Professor DEAN emphasised the value of a close correlation between anatomy, physiology, and pathology Often it was not until the student saw changes in a diseased kidney or lung that he realised he did not know what the normal appearance was a course in the abnormal was something which stimulated a desire to know about the normal, and for that reason Professor Dean would have been happier if pathology and bacteriology had come with human anatomy, physiology, and biochemistry, before medicine

Prof P J MOIR (Leeds) was disappointed that there was no mention of the preregistration year the way that year was used must have a considerable influence In his school they felt that it did away with the need for long clerkships in medicine and surgery It would be possible so to arrange the course as to give some of the more practical parts less influence and use the time in teaching more fundamental matters Some consideration should be given to the function of the preregistration year vis à-vis the undergraduate stage Prof G A CLARK (Crown member) thought that the preregistration year was the responsibility of the licensing bodies but not of the council

Prof T N A JEFFCOATE (Liverpool), replying for the curriculum committee, said he was opposed to mentioning periods if this could be avoided, but the committee thought it important that the old system of apprenticeship should be retained He was a little in sympathy with what had been said about the two-month period for midwifery, but the fact had to be recognised that any practitioner was entitled to practise midwifery It was impossible to teach even very simple matters of safety unless the student was resident for a reasonable period Dr D J A KERR (Royal College of Physicians of Edinburgh) said that the professor of midwifery in Edinburgh would like the specific period of two months deleted and some such words as "a sufficient period" substituted Mr R A STONEY (Royal College of Surgeons in Ireland) thought it useless to make a student resident for less than two months A great deal of his time was taken up in getting used to the routine of hospitals

Professor BROTHERSTON formally moved and Dr KERR seconded, that "sufficient time" should be substituted for "two months" in the period of residence recommended for midwifery Sir HAROLD BOLDERO opposed The stipulation of the number of cases had been removed and he thought they should wait some years

Sir DAVID CAMPBELL said that the committee thought that at least fifteen months in clinical clerkships was desirable and that by keeping the two months while dropping the number of labours they could ensure that students were adequately trained in midwifery He asked the council to reject the amendment It did so, six members voting for the amendment

Replying to other points raised in the discussion Sir David said that the therapeutic uses of drugs were included in pharmacology As to the correlation of pathology and bacteriology with anatomy and physiology, it was recommended that "interdepartmental teaching should be encouraged throughout the whole period of professional study" There was nothing to prevent Professor Dean's school teaching the elements of bacteriology as indicated The preregistration year was not—perhaps unfortunately—the concern of the council It was for the licensing bodies to see that their students received adequate instruction in the preregistration year

On the recommendations as to professional examinations, Sir David mentioned that the curriculum committee would have liked to say that examiners should be compelled to take into account the duly attested records of students, but this recommendation was not possible in the case of bodies which were purely examining bodies

REVIEW OF EXISTING CURRICULA

The revised recommendations, together with the introduction, will be published by the council and circulated to licensing bodies and medical schools No date of operation has been specified, but the council hopes that licensing bodies and medical schools will review their curricula in the light of the new recommendations as soon as they conveniently can

THE PHARMACOPŒIA

Dr GUY DAIN, chairman of the Pharmacopœia Committee, announced the committee's decision that colour should be allowed to be attached to tablets in cases where the preparations were the monopoly of one firm and could not be made by anyone else—and only in those cases This would cover nine items only, and possibly a tenth At present no colour is allowed for any tablet

MEMBERSHIP OF THE COUNCIL

Dr J M O'CONNOR has been appointed representative of the National University of Ireland for three years, and Professor CLARK has been reappointed for five years

Medical Disciplinary Committee

The committee met on May 29, with the President in the chair

APPLICATIONS FOR RESTORATION

Charles Kingsley Colwill, who was not present but was represented by Mr E B McLellan, counsel, instructed by Messrs Le Brasseur and Oakley as solicitors to the Medical Protection Society, applied successfully for the restoration of his name to the Register

An application from *William Arthur Nason*, whose name was erased in 1954, was rejected

POSTPONED JUDGMENTS

To give *William Frank Cruickshank*, registered as c/o Milne, Broxy Cottage Westmuir Brechin, Angus, M.B Glasg (1935), a further opportunity of rehabilitating himself, the committee had postponed judgment a year ago Dr Cruickshank asked for postponement for a further year so that he might obtain suitable references This was agreed

The Registrar was not directed to erase the name of *John Millar Matthew*, registered as of 176, Farley Road, Selsdon, Surrey, M B Camb (1932) Judgment had been postponed for a year

The committee noted with satisfaction the letters sent to the council concerning *James Watson Richmond* registered as of Rosskeen, Kelty, Fife, M B Glasg (1929), in whose case judgment will be given in May, 1958

Andrew Francis Amerherst Gallen, registered as of 20, Orchard Drive, Giffnock M B Glasg (1932), had had judgment postponed for a year In view of satisfactory information as to his conduct the committee decided that his name should not be removed from the Register

James McKenzie, registered as of 255, Rochdale Road, Middleton Manchester, M B Aberd (1944), appeared for judgment, postponed from last May He was represented by Mr N Leigh Taylor, of Messrs Hempsons as solicitors to the Medical and Dental Defence Union of Scotland In view of information as to his conduct, which had been received, his name was not erased

Joseph John McMenemy registered as of Burnside, Bargeddie, Glasgow, L.A H Dubl (1947), had had judgment postponed until the present session He was not present and Mr Taylor, who had had no instructions, explained that he was abroad Judgment was further postponed

In another case in which judgment had been postponed, the committee, for the first time, varied a decision which it had announced

The practitioner concerned was *Robert Lindsay*, registered as of 8, St Ninian Drive, Inverness, M B Glasg (1945), who had been convicted, in 1951, 1952, 1954 and 1955, of committing breaches of the peace and of being found drunk A decision had originally been postponed for a year in May, 1955, in order to give Dr Lindsay an opportunity of reconsidering his habits, and last year the chairman announced that the committee had decided to postpone their judgment for a further period of a year, until May, 1957 "This decision is taken in your own interests," he added

Dr Lindsay was present and was not represented He said he was sorry for everything and hoped things would be better in the future In answer to the chairman, he said that for about ten months he had not been in practice He did not want to say in public what he was doing, for he did not want it bandied all over Scotland

Mr G J K Widgery, solicitor to the council, said there were a number of testimonials The Chairman I do not want them read

The committee deliberated in camera and then the chairman announced that, in Dr Lindsay's own interests, the committee had determined to postpone judgment for a further period of one year He would be asked to furnish the names of professional colleagues and other persons of standing to whom the council would be able to apply for information, to be given confidentially, as to their knowledge of his habits and conduct in the interval

Dr Lindsay Being on probation should not be a hardship There is one difficulty about it If you were in a job it would not be so bad I find it difficult to approach people

The chairman then asked if this was why he was doing his present work

Dr Lindsay I thought it would be a good thing to do work in the open air

The Chairman I wish you had called our attention to that before Do you mean you have difficulty in getting employment because you are on probation ?

Dr Lindsay That is my attitude When I was drinking I had no difficulty It is only since this publicity

Dr Lindsay added that it had cost him £25 coming to the meetings of the committee

The Chairman Would the committee like to consider this in the light of the statement which has now been made by Mr Lindsay and which we had not before us when we discussed this matter ?

Strangers were ordered to withdraw When they were readmitted the chairman announced

"In the light of the statement you made to us just now and after further consideration of this case the committee have now determined that the registrar shall not be directed to erase your name by reason of the convictions That concludes the case May I express the personal hope that you will see to it that you do not appear again ?

Dr Lindsay I thank you very much indeed

CONVICTION FOR SHOOTING

Robert Philip Strang, registered as c/o Hempsons, 33, Henrietta Street, London, W C 2, M R C P (1946) had had judgment postponed for two years in May, 1955, following his conviction, at the Central Criminal Court in 1954, upon indictment of shooting at Edward Anning with intent to do him grievous bodily harm, for which he had been ordered to be imprisoned for 18 months Dr Strang was not present, but was represented by Mr Taylor in his private capacity

Mr Widgery said that there were three testimonials

Mr Taylor read a statutory declaration from Dr Strang which stated that he left England last January with the object of practising medicine overseas He had now succeeded in making a new start and begged the committee to allow him a chance to rehabilitate himself

In view of the information concerning Dr Strang's conduct the committee determined not to erase his name

ADULTERY WITH A PATIENT

Kenneth Leopold George Nobbs, G M, registered as of 3, Cotman Gardens, Edgware, Middlesex, M B Lond (1930), was charged with committing adultery with a woman patient and having been found guilty of adultery with this woman by a decree of the Divorce Court

Mr Widgery, solicitor to the council, alleged that the woman was still on Dr Nobbs's list on Aug 27, 1956, when the adultery took place, which was found proved in the Divorce Court, but in a letter to the council Dr Nobbs said she left his list on Aug 23 He had known the lady and her husband socially, they were on Christian name terms

In evidence Dr Nobbs said that when they knew they were in love he wanted her name transferred from his list—not that they had any intention of adultery, it was purely that he was not treating her properly because he could not treat her objectively

MR WIDGERY I put it to you that the real reason was that you were then planning adultery ?—That was quite untrue It could not be less true Our one idea was to prevent any such occurrence

Mr Taylor of Messrs Hempsons, solicitors for the Medical Defence Union submitted that what occurred arose in no way out of the professional relationship but out of the social relationship, which was, the evidence showed, unusually close in this case It was not wrong for a doctor and patient to develop a very high degree of friendship In the nature of things that friendship sometimes would go too far If that happened between a doctor and his patient the doctor would have sinned, but would he have sinned professionally, any more than if he were a solicitor, an architect, or a candlestick maker ? What was the professional sin in those circumstances ? In this case there was not one jot of evidence that Dr Nobbs had over abused the professional relationship in its narrower sense

In his final address Mr Widgery said

"This lady came to Dr Nobbs as a patient She later became his mistress The best that can be said is that there may have been a gap of four days when she was technically not his patient at any rate for the purpose of the National Health Service regulations before the proved adultery took place on Aug 27 I submit that cannot be any answer to a charge of this nature and also you have the evidence of Mr Hills that Dr Nobbs gave Mrs Hills medical treatment if only first aid, on a date in September'

The committee found the facts proved and that Dr Nobbs was guilty of infamous conduct in a professional respect The Registrar was directed to erase his name This is subject to the entering of an appeal to the Privy Council

CONVICTIONS FOR DRUNKENNESS

Patrick Francis MacDonald, registered as c/o A MacDonald, solicitor, Main Street, Granard, co Longford, M B N U I (1941), admitted being convicted on various occasions since 1950 of charges arising from the influence of drink

The chairman announced that, in the opinion of the committee, the convictions indicated habits which were not only discreditable to Dr MacDonald and to his profession but might be dangerous to his patients To give him an opportunity to overcome his tendency to drink to excess, the committee determined to postpone judgment for one year

CANVASSING CHARGES NOT PROVED

Nancy Winifred Holloway, registered as of Curridge, Newbury, Berks, M R C S (1923), appeared on six charges of *canvassing for the purpose* of obtaining patients, between October, 1954, and March, 1956, but Mr Taylor, of Messrs Hempsons, as solicitors for the Medical Defence Union, who appeared on behalf of the complainant, Dr J A Richards, withdrew three of the charges Dr Holloway was represented by Mr E B McLellan, instructed by Messrs Le Brasseur and Oakley, as solicitors to the Medical Protection Society She denied that she canvassed the persons named in the charge or any other person or persons for the purpose of obtaining patients She had a considerable practice and in any event was proposing to retire

The committee determined that the facts alleged were not proved to their satisfaction and accordingly found Dr Holloway not guilty of infamous conduct in a professional respect

---

Medicine and the Law

Agranulocytosis and a Tranquilliser

A WOMAN of 43 died of agranulocytosis after treatment in a mental hospital with a tranquillising drug, 'Pacatal' At the inquest[1] the coroner remarked that this drug, which could damage the bone marrow, had until recently been freely obtainable at chemists The drug, he added, should be given only to people who were psychotic and then only when all other forms of treatment appeared to be ineffective Because so little was known about the drug, doctors should not use it in general practice

In evidence, a pathologist said that blood counts made during this form of treatment could give a false sense of security because the effects on the marrow could appear suddenly But many people, he continued, could be given the drug without suffering any harm, and he thought it was a recognised treatment in mental hospitals, but it should not have much place in general practice The dose given in this case was not excessive A registrar at the mental hospital told the coroner that the patient could have been treated with phenobarbitone but the calming effect would have been less sure and rapid A verdict of 'death by misadventure" was recorded

Conferences

ANGLO-FRENCH SURGICAL MEETING

British and French surgeons met in London last week at an international conference with a difference. At the invitation of the president and council of the Royal College of Surgeons, the Académie de Chirurgie de Paris were the visitors and members of their party gave all the formal papers. The British contribution was a series of demonstration operations which were televised in colour and were seen by the delegates at the college while they were actually in progress at St Bartholomew's Hospital. The facilities for this were provided by Messrs Smith, Kline, and French Laboratories Ltd.—a service already familiar to North American surgeons.*

The technical quality of the picture was little better than that at a similar demonstration in Chicago in 1949. There is still a curious bluish green over all the images; the skin appears quite corpse like and the shadows opaque, and depth is difficult to judge. The truly stereoscopic effect which is so valuable in colour photography has not yet been achieved. The sound reproduction was often quite indistinct. The production, on the other hand, was excellent. Operations were chosen for their visual interest, and the team of surgeons were acknowledged masters of their special subjects. Each session was under comment by a moderator and a two man panel, and these three, themselves distinguished in the subject under demonstration, kept up an interesting series of questions which the surgeon had to deal with as he went along. The audience, too, could pass up their own queries for answering, so the demonstrators faced quite an inquisition. They were more than equal to it, however, and the defects of the picture were forgotten in the valuable discussion which accompanied it.

The papers were generally most stimulating and impressive—some in French and others in English. There was no translation service, but the quality of the material and slides lessened the need for one. Difficult subjects were included—for example, J. L. **LORTAT-JACOB** on his eleven years' experience of over 700 cases of carcinoma of the œsophagus. His experience has resembled that of most British surgeons who have written on this condition. The number of five year cures is small, but the resectability-rate is high, perhaps because all the operations were through the left chest, and even fixed growths were often removed.

MERLE D'AUBIGNÉ showed a fine colour film of his remarkable operation for reconstructing the knee after local resection of malignant tumours of the lower end of the femur. Replacement is by an ingenious combination of homograft, sliding autograft, and pedicled patella, while an intramedullary nail holds the whole thing together. Patients are able to walk in two to three months. Sarcoma is not a promising tumour for this kind of management, but a special indication may be found in the dangerous type of recurrent osteoclastoma after curettage and radiotherapy.

P. **PORCHER**, whose cineradiographs of the abnormal œsophagus were found so enlightening in this country last year, threw further light on the problem of *ulcères peptiques*, which in French has the narrower meaning of anastomotic ulcers. In his films recognition of the elusive crater in the stomal loop is eased by the curious fixity of the surrounding mucosa, whilst all else is incessantly mobile.

R. **SOUPAULT** showed how the deeper mysteries of the lower end of the common bile-duct may be solved in some cases by a combination of those techniques associated in Britain with the name of Professor Mallet-Guy—per-operative cholangiography and measurement of biliary pressures. Whether or not a stone is present this kind of investigation is yielding important information which may lead to a better understanding of the region.

Anterior approaches to the cervicodorsal spine have been worked out by **JEAN CAUCHOIX** and **JEAN-PAUL BINET**, and the former presented an interesting short paper showing the value of these operations in cases of paraplegia, often after laminectomy has failed. He raised the question of how many intercostal arteries could safely be divided in freeing the aorta; there is still no final answer to this in man.

In pelvic peritoneal reconstruction after Wertheim or other pelvic clearance operations, H. **BOMPART** has found that a long flap or sheet of the lower anterior abdominal peritoneum can be taken back and sewn to the pelvic brim just above the iliac arteries and the rectum. The whole of the pelvic cellular and lymphatic tissue can be removed below this level. A small plastic tube with mechanical suction soon obliterates the space, and the patients recover their abdominal functions correspondingly quickly.

---

[*] As Dr Brian Stanford pointed out last week (p. 1149) this is not, as we had asserted, the first such demonstration in this country. Operations were televised in colour, using British equipment, at the International Congress of Ophthalmology in London in 1950.

Parliament

QUESTION TIME

Royal Commission's Report

Dr **DONALD JOHNSON** asked the Minister of Health if he would make a statement of his policy in regard to the implementation of the recommendations of the report of the Royal Commission on the Laws Relating to Mental Illness and Mental Deficiency.—Mr **DENNIS VOSPER** replied: I welcome this valuable and comprehensive report, and I am at present studying the many recommendations made in it. I must have time to consider them before making any further statement. But I am glad to have this opportunity of expressing the Government's gratitude to the chairman and members of the Royal Commission for undertaking this important inquiry.

Dr **JOHNSON**: Will the Minister take some action, prior to legislation—which we realise must take time—on those recommendations which do not require legislation, particularly the review of patients at present in hospital?—Mr **VOSPER**: Most certainly I shall consider what can be done by administrative means in advance of any legislation.

Mr **KENNETH ROBINSON**: Will the Minister agree that, as a result of the recommendations of the Royal Commission, the present procedures will now give rise to increased anxieties and frustrations on the part of parents, psychiatrists, and patients? Is not that an added reason for early action on the recommendations?—Mr **VOSPER**: That is certainly true, but any legislation will be of a very complicated and prolonged nature and must receive adequate consideration before it is introduced.

Certification

Mr N. E. **DODDS** asked the Minister if he was aware that, of recent years, a much greater use has been made of the one doctor process of certification than of the two doctor process for which the law also provides; and whether, pending the introduction of amending legislation, he would use the resources of his department to give publicity to the existence of the two doctor process of certification.—Mr **VOSPER**: Two medical certificates are required in all cases of certification of mental defectives. In mental illness, relatives or friends of the patient can initiate the procedure involving two medical certificates, and the one certificate procedure can be used only where the duly authorised officer is satisfied that there are no relatives or friends able and willing to initiate action or that the patient is not under proper care and control.

Mr **DODDS**: Does the Minister appreciate that every week now 400 people are certified under the one doctor procedure and the doctor does not need to have any special knowledge of mental illness? As the relatives do not know about these things until long after the deed has been done, can he not see the dangers of this system ?—Mr VOSPER The hon Member said that the relatives do not know, but it may be that they would prefer to use the one certificate procedure In any case, the medical superintendent also examines the patient In considering whether any action should be taken on the administrative side of the proposals made by the Royal Commission, I will look at this point

Private Patients

Mr JOHN HALL asked the Minister if he would now amend the National Health Service Act, 1946, so as to allow private patients to utilise the other facilities provided by the Act, and so as to allow the provision to all private patients free of charge, other than the prescription charge, a selected list of preventive and life saving drugs and drugs designed for the alleviation and treatment of lethal diseases —Mr VOSPER replied The private patients of general practitioners have full access to all the facilities of the National Health Service, other than the supply of drugs as part of general medical services The provision of a selected list of drugs for private patients would raise many problems of great difficulty My predecessor invited the British Medical Association to discuss this matter with the department, and those discussions are about to take place

Cost of Prescriptions

Mr R W SORENSEN asked the Minister if he had now reviewed the effects of increased prescription charges, and what information he had in respect of the decrease in the number of prescriptions and their cost —Mr VOSPER replied Examination of a sample of prescriptions dispensed in December has shown that the increase in average cost of about *5d* was probably due almost entirely to doctors prescribing larger quantities The trend of costs since December suggests that this has continued The number of prescriptions has also been much lower than a year ago, but this must be due partly to the low incidence of sickness Mr SORENSEN Could the Minister indicate to what extent the anticipation of these increases has been fulfilled financially ?—Mr VOSPER So far as I can gather at present, the anticipated saving and the actual saving will be about the same Mr ARTHUR BLENKINSOP Does not the Minister recognise the very real danger of waste involved in prescribing larger quantities, which he himself is encouraging ?—Mr VOSPER I cannot accept that, which suggests that the general practitioner is not competent to exercise discretion The ordering of larger quantities is not wasteful if there is a continuing need It does help people with chronic or continuing illness That, I believe, is what is happening at the moment Dr SUMMERSKILL Would the Minister say it is an overstatement to say that most people have in their bathroom cupboards unused tablets, lotions and ointments which have cost the country a great amount of money ?—Mr VOSPER I have seen allegations to that effect, but I have no evidence that it is true

Radiostrontium in Bone

Mr D HOWELL asked the Prime Minister what advice he had received from his medical and scientific advisers about the fact contained in the report of the Atomic Energy Research Survey that the bones of a stillborn child in Carlisle contained about seven times as much radiostrontium as that found in older people examined at about the same time

Mr MACMILLAN replied that the heavier concentration of radiostrontium in the bones of children compared with adults was fully considered in the M R C report It was for this and other cognate reasons that the maximum permissible level of radiostrontium in the human skeleton accepted by the International Commission on Radiological Protection was regarded as being too high for the general population The Medical Research Council considered that the maximum concentration of radiostrontium in the bones of the general population with its proportion of young children, should not be greater than a tenth of the maximum permissible level for adults in special occupations

Mr HOWELL asked whether it was not disturbing to find such quantities of strontium in a baby that has neither breathed nor fed ? Because the M R C report showed that babies up to one year of age already had 1 2 units of strontium, and because of the growing medical and scientific perturbation about this, would not the Prime Minister refer this matter specifically to his advisers

Mr MACMILLAN pointed out that, in the case mentioned the figure was 0 47 unit That was still a hundred times less than the average allowable level of the amount of radiostrontium in the bones of both children and adults

Expenditure on Social Services

Mr G P STEVENS asked the Chancellor of the Exchequer how the increase in expenditure on the social services by the central government the National Insurance Fund, and the local authorities between 1951–52 and 1956–57 compared with the rise in retail prices during the same period —Mr J ENOCH POWELL, the financial secretary to the Treasury, replied Between 1951–52 and 1956–57 expenditure on the social services increased by 38% and retail prices by about 23% Mr STEVENS I ask my hon Friend whether he agrees that despite economic difficulties in the past few years, there has been a very substantial advance in the provision of real social services for the people ?—Mr POWELL Yes, Sir Mr ARTHUR BLENKINSOP Does not the hon Gentleman also recognise that a very large part of any increased expenditure is in fact due to rises in prices, and that the real increases in the value of the services are extremely limited ?—Mr POWELL That does not detract from the fact that there has been a substantial increase in real terms over the period—about 12½%

Mental Illness outside the Hospital

In England and Wales the attendances at psychiatric outpatient clinics were 523,000 in 1950 and 714,000 in 1955 The number of domiciliary psychiatric visits in 1950 was 5600 and in 1955 11,200

Some Hospital Figures

In England and Wales, altogether 474,000 patients were on waiting lists in 1954, and 455,000 in 1955 The provisional figure for 1956 is 430,000 Though there has been an improvement in the E N T section, that and general surgery still have the longest waiting lists

The annual number of patients per allocated bed in hospitals other than mental hospitals, for 1954 was 13 1, for 1955, 13 2 for 1956, 13 4

Public Health

Influenza in the Far East

IN addition to the countries which we mentioned last week,[1] outbreaks of influenza have now been reported from India (Madras and Bombay), Cambodia, Indonesia, *Sarawak, and North Borneo* Epidemics continue to be widespread, but the disease itself has remained mild In a ship recently arrived in Rotterdam from the Far East 30 % of those aboard had had influenza By the time the ship reached Rotterdam the outbreak appeared to have died out So far there is no news of outbreaks in the Northern hemisphere, where epidemic influenza usually breaks out in the winter months

In England Now

A Running Commentary by Peripatetic Correspondents

ON arriving at Euston, I had ten minutes to get to the Royal College of Physicians When I asked the taxi-driver to take me there he said "Is that the one in Lincoln's Inn Fields or is it the one where the gentleman who discovered the circulation of the blood is over the entrance ?" He said that he was sorry that he had forgotten the name of this doctor and I informed him that it was Harvey, but I was not sure enough of my facts to tell him that it was Linacre who stood over the door and that Harvey was in a niche on his left In 1957, 300 years after his death it is pleasant to think that the man in the street looks up to the discoverer of hæmodynamics

* * *

A meeting of the British Society of Deviation Medicine was held on April 1, at the National Deviation Hospital, with Sir CYRIL OBLIQUE (London) the president in the chair His presidential address, entitled Fifty Years of Deviation Medicine, embodied a succinct and inspiring account of the principles underlying this concept of medicine Sir Cyril, however, pinpointed the main problem facing the modern deviationist if the object of the practitioner was to treat all organs but that affected, how should he tackle such generalised conditions as polyserositis and subacute lassitude ?

Dr A ZIGZAG (Isle of Dogs) said that treatment of the whole man was a heresy into which deviatric and adeviatric doctors were equally likely to fall he went on to enlarge on the distinctions between deviatrics and deviatology

Dr I L FLYOFF (Novokhruschevograd), spoke as official observer from UNDO He thought psychodeviatrics was the answer to many such problems In his clinic, the attempt to limit therapy to unaffected organs was considered an insufficient safeguard psychosomatic parallelism demanded that the mind should be the sole recipient of treatment in bodily disease, and vis-à-vis

Mr STEER CLEAR (Land's End) gave a clinical demonstration of the results of deviatric surgery His thesis—that classical eccentric therapy may leave much to be desired—was amply borne out by a case-demonstration of a gangrenous foot from which the patient had been enucleated

Dr O CIRCUIT-JONES (Ysptty Chwith) then gave a paper on deviapædiatrics Prophylactic treatment, he said, should be begun in utero The danger of contaminating pathological tissues was being met in Wales by the use of isotope-containing polypharmaceuticals Mr G RICH QUICK (Mayfair) said that gynæcology offered a particularly promising field for the indirect approach and Dr ASHTON (Ashton-under-Lyne) underlined what had been said

* * *

A mild form of blackmail, which seems to be on the increase, is to send with a begging letter a stamped addressed envelope. When this envelope is of the "business reply" type, with the two vertical black lines on its right-hand side, the appeal to one's generosity is weak, but when the envelope bears an unfranked 2½*d* postage stamp, something prevents you from depositing it in the W P B As a result it lies for several days on top of your desk, a perpetual challenge, until you are finally forced to a decision You think here is a poor charity that has actually expended 2½*d* in hard cash and therefore you are in duty bound to use the envelope, so you send a donation

This can become chronic but there is a cure To achieve it you have to tear the 2½*d* stamp off the envelope and place it in your stamp-drawer for later soaking-off when you have run out of stock This first removal of a stamp produces immune bodies, and thereafter no effort of will, or appeasement of conscience, is needed to remove the stamps from subsequent envelopes As there is no appropriate heading in your income-tax form to record the annual profit so derived, it is not subject to tax—as yet

* * *

Things are not what they seem in our prem unit Outwardly, all the babes are neatly labelled with the names of their mothers choosing, with a card at the head of cot or incubator enabling the correct infant to be pointed out to proud father or grandma But underneath the surface, things are different Sister has her own labelling system For instance there is no mention of Keith Maldwyn P on many pages of the ward record-books Sister doesn't much care for either Keith or Maldwyn as forenames (as the G P O would now call them), and she just doesn't use them Instead, she likes Oscar and Michael ("Because he's small, so it suits him") All this means that Michael is liable to appear perplexingly in a list of Wts and Temps with no surname at all, and when there's *no baby of that name in the unit* If this system is carried to its logical (or illogical) conclusion we shall need a new ward book with tables showing both Sister's and parents' versions of every baby's name

Even the waste-bins have been affected by this cryptographic disease Whereas the right-hand bin labelled "LINEN" actually contains linen-waste, the left hand bin is also labelled "LINEN," but is really intended for paper-waste Somewhere, I suppose, there must be a pair of PAPER bins of equally mixed contents

It's all very confusing

* * *

Peripatetic correspondents should help each other, and I hope that Bill's father and Pam's doctor (see this column last week) will get together, with Bill in the chair It would not take Bill very long to advise Pam's doctor (with Bill's father as interpreter), and I suspect that Pam's doctor would scribble "Cortisone" on the back of an envelope and dash back to his evening surgery with his mind at rest

* * *

The bronchoscopist was also an enthusiastic yachtsman As he demonstrated to us the opening of the upper-lobe bronchus he remarked, "You will usually find it half an inch past the carina on the starboard wall of the main bronchus A somewhat scholarly physician took the wind from his sails when the patient's X ray was inspected a few minutes later The lung markings on the sinister side are more prominent than those on the dexter" he said

* * *

He is a diabetic, a pleasant fellow long accustomed to the courtesies of the profession He does not give his physicians at all times their full titles "Dr So-and-So" but calls each simply "Doctor" Recently he has had to have a lung resection What more natural, then, that he should address me and a fellow surgeon each simply as "Mister" ?

Letters to the Editor

STEATORRHŒA AND HYPOPARATHYROIDISM

SIR,—I am very glad to note that Dr Jackson (May 25) has drawn further attention to the occasional finding of biochemical signs suggestive of hypoparathyroidism in cases of steatorrhœa, and I entirely agree that we should all look out for more cases of this kind, and for opportunities to investigate them further However, I write to add to his letter that not only should one carefully consider plasma levels of calcium and phosphorus in such cases, but also the skeletal X rays in some detail For this latter purpose Dr C J Hodson and I have for some time standardised the procedure of taking X rays of the ' abbreviated skeleton " as we call it this comprises lateral skull, chest postero-anterior view (for ribs and scapulæ), both hands and wrists, straight picture of abdomen and renal tract (for kidneys), lateral lumbar spine, pelvis and hips, both knees antero posterior Such a routine procedure covers most of the best sites where signs of osteomalacia and/or hyperparathyroidism are likely to be detectable It is important to preserve X rays that are apparently negative at the time since comparison with subsequent X rays after suitable treatment of the patient will sometimes show that signs of metabolic bone disease were originally present, though not then diagnosable

My special reason for suggesting this is that we are now studying two patients who have shown simultaneously and over a period of at least some months biochemical signs of hypoparathyroidism (low calcium, high phosphorus) and radiological signs considered specific for hyperparathyroidism (subperiosteal erosions, &c) as well as a high plasma alkaline phosphatase In one of these cases marked steatorrhœa was present and the patient was obviously a survivor of cœliac disease from childhood In the other patient no steatorrhœa, renal failure, or any other disease could be discovered In both cases, vitamin D cured simultaneously the signs of hypo- and of hyper parathyroidism

This situation seems even more curious than that raised by Dr Jackson, and will presumably have to be explained only by destroying one of our present concepts Perhaps our diagnostic criteria for hypo or hyper parathyroidism are wrong , perhaps there is more than one parathyroid hormone and sometimes one can be increased and the other decreased Whatever the explanation, we should like to draw people's attention to this possibility We shall not publish our cases until the follow-up has lasted a bit longer

For this particular disease I can only suggest the name " *hypo-hyperparathyroidism* with and without steatorrhœa "—the precedent for rather unusual nomenclature in this field having been firmly set at Boston, Mass

FATAL CARDIAC ARREST WITH FLUOTHANE

SIR,—Dr Foster has done a great service by his letter of June 1, if only by drawing attention to errors in the use of ' Fluothane ' (halothane)

All the literature to date points out that concentrations of up to 2% or, in the very robust, 3% are adequate to produce the optimum effects I hesitate to think what concentration was obtained by putting it in the ether container of a Boyle's type II circle absorber, and putting the lever to the sixth notch. I have heard of a fatal case during a similar operation where a similar technique was used with ether

I have used fluothane in a closed circuit, vaporising it in a Rowbotham attachment With the lever " full on " this gives 3 8% concentration, which is rarely necessary Warning has also already been given about attempting to produce full abdominal relaxation with fluothane, the use of succinylcholine chloride being advised. The same paper [1] also warns against using gallamine or tubocurarine with fluothane

It will be a pity if this apparently useful addition to the anæsthetist's armamentarium were to be condemned on insufficient grounds

Worthing

F R GUSTERSON

SIR,—It was with the deepest regret that I read the first account of a fatal cardiac arrest under ' Fluothane ' (halothane) anæsthesia I agree that it is impossible, in the absence of an electrocardiographic tracing of the collapse, to determine the cause of the fatal outcome Vagal arrest is a strong possibility, however, as the patient was suffering from a condition associated with increased vagal activity

The anæsthetic technique described by Dr Foster is remarkably similar to one which I have used to induce vagal inhibition and arrest of the human heart with cyclopropane, ether, and trichlorethylene—positive pressure insufflation of these vapours into the lungs of non atropinised patients [2,3] I am quite certain that fluothane in man is equally if not more effective in producing cardiac arrest in this way This type of arrest is completely preventable by adequate atropinisation and it is most unwise to assume that it is due to a toxic effect on the heart Scopolamine is not a suitable substitute for atropine [4] and there is no evidence to indicate that gallamine would be a suitable alternative

Dr Foster has been wise in drawing attention to the hazards of using fluothane in uncalibrated vaporisers incorporated in closed circuits, since unnecessarily high vapour concentrations must inevitably be attained, particularly when the gases are warmed by soda lime The importance of restricting the vapour concentration to 2% or less has already been stressed The hypotension sometimes associated with fluothane anæsthesia has been no more difficult to control than that associated with spinal analgesia , if considered necessary it can be prevented by a suitable vasopressor, even during deep fluothane anæsthesia

I should have thought that Dr Foster would have been convinced by recent experimental and clinical reports that fluothane has little if any pharmacological resemblance to chloroform or any other volatile anæsthetic agent My case of non fatal syncope, to which he refers, was described in order to illustrate the dangers of simultaneously using drugs pharmacologically incompatible with fluothane and was essentially an example of the mismanagement of a patient under fluothane anæsthesia , it did not reflect in any way on the efficiency of fluothane as an anæsthetic agent

I should like to assure Dr Foster that, far from being " onerous," the patients, surgeons, nursing staff, colleagues, other " sponsors " and I have found fluothane to be a delightful anæsthetic agent in many respects I admit that we have encountered some mildly unpleasant reactions but, in each instance, they have been related to errors of technique rather than to any inherent pharmacological defect in the drug

SMOKING AND LUNG CANCER

SIR,—New evidence about the link between excessive smoking and lung cancer is likely to be published soon

One thing is certain · the enormous increase in lung cancer is closely allied to the increase in the smoking of Virginian cigarettes It is striking that cigar smokers do not show a similar increase in lung cancer Nor do we hear of the growth of lung cancer in countries where they smoke just as much as in this country but non-Virginian tobacco

Virginian tobacco is different from any other, not only in its mass production and harvesting, but also in the way it is cured Statistics show that the arsenical content of various brands of American cigarettes has increased threefold in the past twenty years This rise is attributed to the use of arsenical pesticides widely used on American tobacco plantations Sales and production records show that cigarette smoking has also increased in the same proportion during the same period And at the end of 1954 statistics illustrate that the death-rates from lung cancer in the United States had risen by 200% in women and 600% in men[1] Similar figures are available in countries where smoking of Virginian tobacco became fashionable only after the wars when it was introduced by the American and British armies of occupation

These facts surely suggest that the relationship between lung cancer and smoking incriminates Virginian tobacco rather than tobacco in general

ALBERT W BAUER

CLICKING PNEUMOTHORAX

SIR,—The case described by Dr Bourne in his paper of June 1 reminds me of a personal experience in 1950 The sharp pain was situated behind the left shoulder and in the left side of the chest It was only moderately severe I was persuaded to have a chest film taken after a colleague had confirmed the clicking noise which I could hear when sitting back in a chair The ordinary postero-anterior film in full inspiration did not show the pneumothorax, which was visible when a second film was taken in full expiration

I believe that clicking is unusual in left- or right-sided artificial pneumothorax, and in small right-sided spontaneous pneumothorax This suggests that the volume of air on the left side is the deciding factor The very small effusion of fluid or blood which goes with it may make the pleural surfaces sticky In the leaning-back position the air pocket will move forwards as the lung sinks back into the posterior costodiaphragmatic trough The movement of the heart then causes the clicking sound If this is the right explanation there is no need to postulate mediastinal emphysema, in which condition air rises into the neck behind the deep cervical fascia This together with severe precordial pain and loud crunching noises constitute Hamman's syndrome of mediastinal emphysema[2]

The sites of reference of the pleuritic pain in Dr Bourne's patient suggest that the air had in fact passed up over the lung to the apex and laterally Perhaps a film taken in full expiration, when the apex of the lung would be at its lowest point under a pneumothorax in the absence of gross adhesions, might have demonstrated the presence of air

X RAYS AND LEUKÆMIA

SIR,—I was interested in the report by Dr. Stewart and her colleagues[1] and in the following discussion, in view of our survey since 1950 of many diagnostic radiological installations in the metropolitan area of New York City and North Jersey, and of the practices of the operators of these units, and of a study now in press (with Dr Robert Berman) detailing intravaginal measurements of the dose of radiation delivered to a group of patients during X-ray pelvimetry and hysterosalpingography.

Discussion of the varied problems concerning human somatic and genetic effects of ionising radiation is often maintained on a rather high emotional level Definitive answers are eagerly sought, but unfortunately there are none at present We are, however, treated too often to a plethora of publicised views and counter-views by more or less assured "experts," who have slight hesitation in asserting their non-disprovable opinions, particularly about the effects of fallout. There are serious limitations to our knowledge, which is admittedly missing or fragmentary in many areas, and until more secure information is at hand there must be a continuing and enhanced educational campaign urging (perhaps ultimately demanding) increasingly higher standards of care and usage by those employing any type of radiation-emitting equipment or material in industry, government, and public health Valuable information about radiological protection has long been available, but its dissemination and resultant impact has clearly not been as extensive as necessary

Care in writing and speaking about radiation and man is very important today because of a heightened interest among a public which cannot know whether opinions spread via mass communication media, have firm or insubstantial grounds Dr Reid[2] refers to the fear-engendering publicity in England following the report of the Stewart group in which information was presented suggesting that an "apparently harmless examination [X-ray pelvimetry] may occasionally cause leukæmia or cancer in the unborn child" manifest in the first decade of childhood The press reaction was to be expected, as with any dramatic announcement, but we may wonder just what was gained by the publication of this "preliminary analysis" of the approximate initial third of the prospective data of a potentially valuable epidemiological survey The data were few, and detailed supporting information was scarce My misgivings over the treatment of this initial material will still exist, even if the final report of Dr Stewart and her group convincingly implicates radiological pelvimetry as having a significant rôle in the development of childhood malignancy It is difficult to have to admonish the admonishers when one has frequently been linked with them

The paucity of supporting information in the interim report led to requests in succeeding issues of *The Lancet* for additional data There have been requests for information about the time in pregnancy when the examinations were made, about the number of mothers who received sulphonamides or antibiotics during the relevant pregnancies, and whether the children of the case and control groups were matched for birth rank Subsequently[3] (but not in the original report) we were told that the children "were deliberately *not* matched for birth rank," and further that "the exact dates and estimates of ionising radiation have still to be determined But since most of the photographing was done for twins, breeches, disproportion, and placenta prævia most of the films were taken after the 30th week" Because of the possibility of critical periods in fœtal radiosensitivity, more precise information would be welcome (From two to five radiographs may be taken in a pelvimetric study, not all portions of a late term fœtus are equally exposed in every film, and the dose delivered to the fœtus can vary by factors of two or more) May I request additional information ? *It is insufficient to note that approximately* equal numbers of children in the case and control groups had received postnatal diagnostic exposures We should ask when they were exposed, what was the type of examination were single or multiple films used, how many children received more than one diagnostic study, and what were the dosages involved in these examinations Such data will be difficult to secure, or may be unobtainable in many instances, but without them we cannot consider this variable (i e , postnatal radiographic examination) as *having a lesser role than* diagnostic pelvimetry, or no rôle, in the ætiology of malignant disease in childhood Without complete information, should we accept the statement that " although they are alike in other respects, there is one important difference between the children who died and their controls the number of mothers who had an X ray of their abdomen during the relevant pregnancy was 85 for the cases and only 45 for the controls " ?[1] Equal numbers on two sides of a ledger do not necessarily connote likeness of treatment or exposure *We should also like to have information* as complete as possible on the history and kind of infectious processes in all the survey children

---

[1] Stewart A. Webb J Giles D Hewitt, D *Lancet* 1956, ii, 447
[2] Reid F *Ibid* Feb 23, 1957 p 428
[3] Stewart A. *Ibid* 1956 ii 573

The future may vindicate the wisdom of Dr Stewart and her colleagues, but on the basis of what was initially presented, as well as what was lacking, the conclusion regarding X-ray pelvimetry is hardly firm

A genetic component in the onset and development of leukæmia[4 5] (and other pathological conditions) cannot be *overlooked, and the Stewart group has noted this possibility* The fact that a genetic factor or factors may have more or less ætiological significance warrants consideration in the selection of appropriate controls If feasible, it would have been valuable in the present instance to secure data about the sisters (and their progeny) of the mothers of the dead children Parents with a common genetic background would thus be used in the quest for an environmental agent or agents important in the initiation of childhood malignancy In other studies concerned with the effects of progeny on parental exposure[6 7] to radiation, more significant information could have been obtained had siblings of like sex been used as control parents

I regret having to present this criticism of a well-motivated group of investigators engaged in a difficult and potentially important study The tempo of discussion regarding somatic and genetic risk from ionising radiation derived from different sources has quickened in the past year or two, and perhaps criticism at this time is as necessary as continued research In the United States we have too many voices making quantitative prognostications with respect to radiation effects in man at a time when quantitation is hardly in order A " popular " subject is attractive and quantitation lends an air of authority

MALARIA IN RUMANIA

SIR,—*Your account* (May 25) of the medical congress in Rumania last month mentioned that malaria has been virtually eradicated The following figures show the result of the campaign against this disease over the past nine years

	No of cases		*No of cases*
1948	338 198	1953	3114
1949	233 962	1954	916
1950	95 469	1955	376
1951	42 025	1956	259
1952	14 217		

The success of the campaign has been brought about by spraying the houses once a year with either dicophane (D D T) or gammabenzene hexachloride (B H C) against the adult anopheles, and also by schizontocidal treatment and chemoprophylaxis among the population It is confidently believed that during the next two or three years malaria in the whole of Rumania will be eradicated It may be interesting to record that Professor Sergheev, of the Soviet Union, said that there were 4,800,000 cases of malaria in the Russian fighting services during the late war Unlike the British and American troops who were engaged in campaigns in highly malarious tropical countries, the Russians were confined to Europe—which shows, not for the first time in history, how serious malaria in Eastern Europe can be in a military campaign

WORLD HEALTH ASSEMBLY

SIR,—Your note of June 1 about W H O is rather misleading in its second paragraph The proposal for the ban on atomic bomb tests was put forward by one of the member States

The World Federation for Mental Health, which is mentioned in the preceding sentence, has had nothing to do with this We have drawn the attention of W H O and various other agencies to the need for the study of mental health problems in connection with the *peaceful uses* of atomic energy This, it would seem, is not made quite clear in your note

World Federation for Mental Health,
London, W 1 J R REES

MEDICAL STAFFS OF MENTAL HOSPITALS

SIR,—With great pleasure, but unhappily with small hope, I support the plea re stated by Dr Strauss and others (May 4) for a substantial increase in the medical staffs of mental and mental deficiency hospitals, although, despite the truth of what they write about inadequate buildings, I wish they had kept to the essential defect *in the psychiatric services of today—the painfully* made quate number of available trained staff I have had plenty of experience in large mental hospitals and write with that in mind, but my points can best be illustrated by reference to the small 67-bedded psychiatric hospital in which I work

Since 1946 the hospital has enjoyed almost all the aims of a progressive mental hospital, in terms of appearance, situation, lack of sex discrimination, complete absence of legal orders, 100% parole, and almost unlimited visiting (made possible by the absorbent benevolence of Holloway Sanatorium, Virginia Water, as an invisible support, even though its services are rarely required)

Over recent years the psychiatric staff has been increased from 2 to 4 During the same time the number of admissions and the number of new *outpatients* has increased very little, only the outpatient attendances have increased significantly (roughly about four times) About a third of the admissions come from a distance, but this letter is concerned with the other two thirds who are local, most of whom have been deteriorating for some time despite monthly or so psychiatric interviews elsewhere, the *maximum* attention which can possibly be given by the number of local psychiatrists available Many are ill for long periods only because of the delay in providing proper treatment, but *as a rule* such patients improve rapidly with three interviews a week and could leave hospital in a *few weeks*, but here comes the rub *If* improvement is *to go on*, interviews must *continue* at least twice weekly, and if the patient is discharged from hospital there is a waiting-list from which another admission can be chosen for the same process to be repeated The factual results are (1) the *hospital* always has an average of about *17* empty *beds*, (2) quite a number of *resident* patients could easily leave at any time if staff were available to deal with new admissions (I would estimate that the bed space is used at about a third of its capacity), and (3) the morale of ancillary staff is reduced because of the *obvious lack*

---

4 Anderson R C *Amer J Dis Child* 1951 81, 313
5 Johnson M J F Peters C H *J Amer med Ass* 1957, 163 20
6 Macht, S H , Lawrence P S *Amer J Roentgenol* 1955, 73 442
7 Crow, J F *Ibid*, p 467

of urgency and the repetitive nature of so much of the work I am informed that the "official" view is that since there are empty beds there is clearly no need of further staff! The hospital has no psychologist keeps its one psychiatric social worker post filled with difficulty, and is short of nurses, so much so that treatment obviously indicated, such as prolonged narcosis &c, has often to be put off

The situation cries out for some authority, in practice completely lacking which can integrate the hospital into a wider scheme of mental health service The money being spent on schemes now afoot for increasing the bed accommodation could be used to gauge the effect of adequate staff for an experimental period of several years

St Ann's Hospital,
Canford Cliffs Dorset

D N. PARFITT

SURGERY OF CHRONIC PANCREATITIS

SIR,—In your account (May 18) of a recent meeting at the Royal Society of Medicine, at which chronic relapsing pancreatitis was discussed the term "caudal pancreaticojejunostomy" is applied to the operation of removal of the left part of the gland and the implantation of the cut end into a Roux loop of jejunum

When Dr J. Buckwalter and I described this operation, in order to distinguish it from the pancreaticojejunostomy previously described by Dr R B Cattell we selected the title "retrograde pancreaticojejunostomy" as the least imperfect of several imperfect alternatives

The term "caudal pancreaticojejunostomy" implies that the tip of the tail of the gland is amputated and the cut end implanted into the jejunum The tail of the pancreas is really very short It is that narrow part of the gland which lies between the two layers of the lieno-renal ligament in contact with the inferior part of the gastric surface of the spleen In none of the cases in which we have done this operation has it been convenient to implant the tail of the gland into the jejunum The gland has always been transected through the body or, preferably through the neck, and it is the body or neck that has been implanted into the jejunum The operation of pancreaticolithotomy has sometimes to be done as a preliminary to pancreaticojejunostomy and it is not possible to scoop our stones from the head of the gland by way of an incision across the tail if the term 'tail' is restricted, as the anatomists restrict it to the part of the pancreas which lies between the layers of the lieno renal ligament In order to avoid a rather difficult distinction between "caudal pancreaticojejunostomy" and corporal" or "cervical pancreaticojejunostomy I would plead that the title 'retrograde pancreaticojejunostomy" be retained

Postgraduate Medical School of London
London W 12

IAN AIRD

CIRCUMCISION WITH BONE-CUTTERS

"SIR,—The method of circumcision performed with the aid of bone-cutters has very much to be said in its favour but many house-surgeons are loth to use it on account of the fear of accidentally removing the terminal part of the glans Moreover, through this not unfounded fear they may be over cautious when using this method only to find that insufficient foreskin has been removed. This is due to the fact that when the bone cutters are applied, it is difficult to feel the glans on account of the rounded blades of the bone cutters precluding the fingers

I have found that if the bone-cutters are applied initially in reverse (i e, with the flat surface proximal), the glans can be palpated easily during the application and there is no hazard of it being involved After one minute the cutters are removed and reapplied on the crushed foreskin with the flat part of the blade now distal. After a further two minutes the surplus skin is excised in the usual manner

St Bartholomew's Hospital
London E C 1

DAVID B L SKEGGS.

PROPHYLACTIC VALUE OF TYPHOID VACCINE

SIR,—The World Health Organisation's reports of field trials of typhoid vaccine in Yugoslavia[1] prompt me to write on our Indian experience with T.A.B inoculation The data which follow are taken from the reports of the health of the army, which are particularly informative because (a) the T.A.B inoculation-state of the army is always at least 80%; (b) the means of laboratory diagnosis is about as good as one could hope for in any controlled field trials; and (c) this community represents a comprehensive cross-section of the population in India

In the war years 1940–45, sanitary facilities were often inadequate for the rapidly expanding Forces Large numbers of recruits from all parts of India were camped in jungle areas where often the only source of water was shallow wells or ponds The incidence of the dysentery and diarrhœa group of diseases steadily increased the rate amongst Indian troops (418 per 10 000) being more than double that before 1940. But in the same period only 5 Indian soldiers in every 10,000 had enteric fever—a remarkable tribute to the value of preventive inoculation with T.A.B vaccine. Hardly thirty years ago, typhoid was one of the principal diseases among soldiers

In 1947 only 2 soldiers out of every 10 000 had enteric fever, though in those days of partition there were unprecedented movements of population in Northern India involving millions of refugees, among whom epidemics were rife and our troops were concentrated in the affected areas under very unhygienic conditions In the same year 355 soldiers out of every 10,000 had an illness of the dysentery and diarrhœa group, for which no prophylactic vaccine exists

The report on the health of the army for 1950–52 gives the incidence of enteric fevers as 1 3, 1 6, and 1 8 per 10,000 for the years 1950, 1951, and 1952 respectively During the same years the incidence of dysentery was 65 6, 55 4, and 47 6 per 10 000, and of diarrhœa from other causes, including enteritis, 83 1, 95 6, and 63 0 per 10,000

British experience in India is equally impressive In 1930–34 admissions of British troops to hospital for enteric fever were of the order of 30 in 10,000; in 1935–39 the figure was 13 in 1940–44 it was 11, and in 1945 it was down to 7 During the same periods the incidence of the dysentery and diarrhœa group of diseases was 406, 435 987, and 1229 per 10,000 per annum respectively

T A B vaccine used for the protection of Indian troops is a heat killed phenolised vaccine prepared by the Central Research Institute, Kasauli, from locally isolated smooth strains which are renewed at intervals The present evidence justifies the faith of the army authorities in phenolised T A B vaccine In this connection it is interesting to record the following statement of the Director of Medical Services in India in 1945[2]

> Following the sharp rise in the incidence of the enteric fevers among British troops in 1942, a rise which was not shared by the Indian troops it was decided that every British soldier as soon as possible after his arrival in India, should be given a boosting dose of 0 5 c c of the Kasauli vaccine, irrespective of when he had last been inoculated with the Home T.A.B vaccine That this policy was sound is not contradicted by the incidence of enteric fevers in 1943 During 1943 typhoid had decreased from 16 per 10,000 in the previous year to 7 per 10 000

---

[1] Chron Wld Hlth Org 1956 10, 153

[2] Annual Report Health of the Army in India, 1943, 6 Pt. 1, p 16

Alcoholised T A B vaccine was never adopted for the Armed Forces in India

The decline in the incidence of typhoid fevers following prophylactic immunisation is considered one of the greatest achievements of preventive medicine today Better sanitation and improved environmental hygiene do not entirely account for the low incidence of typhoid fevers under conditions which show a striking increase in other bowel diseases

India House, London M L AHUJA

TO COMFORT ALWAYS

SIR,—It appears that that doughty crusader, Dr Learoyd (June 1), misunderstood what Sir Frederick Armer meant to convey in his recent address (May 18, p 1031)—namely, that the *proportion* of patients voluntarily seeking aid at our mental hospitals has gone up by leaps and bounds these past ten years, surely a welcome fact It is sad to think that a colleague who means and writes so well must express himself so unfortunately, all along, when it comes to psychiatry

But for correspondence in your columns, Sir, few of us would be able to quote (more or less aptly) the grand *guérir quelquefois, soulager souvent, consoler toujours,* which, as pointed out by your correspondents,[1] goes back to Hippocrates It is meant to comfort the physician, the tone being on guérir

Isleworth Middlesex H PULLAR STRECKER

DUODENAL ULCER TREATED BY GASTRO-ENTEROSTOMY WITH VAGOTOMY

SIR,—It is not for me to comment on the surgical aspect of Mr Hindmarsh's paper last week, but attention must be drawn to the reasons advanced in justification of the method of gastro enterostomy with vagotomy, because the deductions drawn from the results of experimental ulcer are not applicable to the spontaneous chronic ulcer as seen in man and are, therefore, inadmissible and misleading

Mr Hindmarsh says that "there is much evidence that the main factor in the causation of duodenal ulcer is the presence of unbuffered gastric acid combined with the free pepsin produced by psychic or nervous stimulation" and that "the flow of gastric juice under nervous stimulation may in itself produce the ulcer" I am unaware of any evidence in support of this assertion

The experimental evidence to which he refers shows clearly that the ulcers which are produced by the action of hydrochloric acid are exclusively formed in the alkaline milieu and have no relation whatsoever to the ulcer of the first part of the duodenum which has an acid milieu It is imperative to make this fundamental distinction in the location of the ulcer because for the ulcers which occur in the *alkaline* milieu—namely, the anastomotic, œsophageal, and Meckel's diverticulum ulcers—the action of hydrochloric acid by itself is sufficient to produce the lesion and its complications, whereas in contradistinction to the ulcers of the "ulcer-bearing area" which occur in an *acid* milieu, the action of hydrochloric acid by itself is not sufficient to produce the lesion A priori, it is not conceivable that any cell secretes a substance which by its own action may ultimately lead to its own destruction

An analogous situation may be observed in respect of bile, which performs its physiological function while it remains in its own milieu, the small intestine, but is violently destructive when it invades the stomach

Detailed evidence in support of this point of view will be found in a recently published monograph[2]

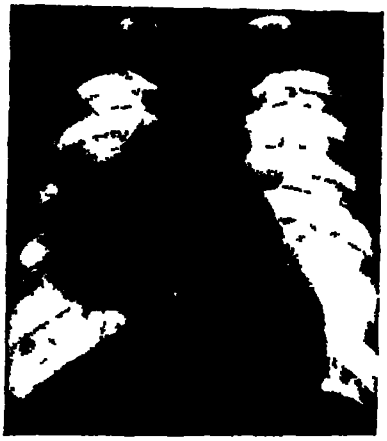
DERMOID OF THE CHEST

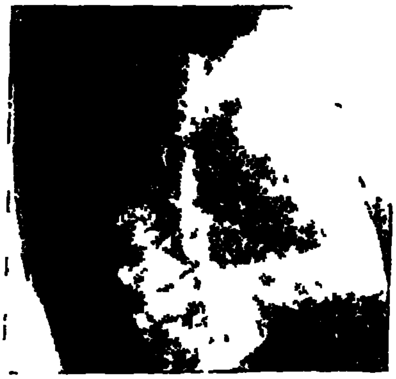
SIR,—Willis[1] defines a teratoma as "a true tumour or neoplasm composed of multiple tissues foreign to the part in which it arises" In the mediastinum a teratoma is almost always a benign cystic tumour of the anterior portion "Dermoid cyst" is a synonym for benign cystic teratoma Of 146 dermoid cysts seen in 1930-52 at the Lahey Clinic, only 2 were in the chest[2]

All teratomas are probably congenital, but, because of their situation and small size at birth, mediastinal teratomas are rarely discovered much before the end of the second decade of life, and sometimes not until after the third decade They grow slowly and accumulate hair, skin, bone, cartilage, teeth, and sebaceous material A mediastinal dermoid rarely gives rise to symptoms unless it ruptures,[3] and it is often an incidental finding in chest films taken for unrelated symptoms, or during a routine survey It was in this way that the following case came to light



A man, aged 27, was radiographed in Germany on March 26, 1956, with all the other people at the hostel where he was living An opaque mass was found in the right side of the chest, and I saw him in England on April 9

He had no symptoms Nothing abnormal had been seen in chest radiographs in 1948, 1949, and 1953 By courtesy of Dr W D R Thompson, medical director of the mass radiography unit, Pine Street, London, E C 1, I was able to see the one taken in October, 1953 Dr J McLaren, of St Thomas's Hospital, also saw this and considered it normal



The patient was admitted to St Thomas's Hospital on April 24, 1956 He had no physical signs The X ray appearances were those of a dermoid cyst in the anterior mediastinum The outline of the cyst was lobulated There was no evidence of calcification or teeth Tomography showed three areas of bone or calcification in one of the smaller lobules lying medially at the bottom There was also some peripheral diminution in density which could represent fat or sebaceous material, or possibly some necrosis breaking down Two male toad tests were negative and so were Wassermann and Kahn reactions Full blood count, erythrocyte sedimentation rate, and electrocardiogram were all normal

On April 30 he was operated upon by Mr N R Barrett The dermoid was larger than had been expected and was very firmly adherent to all structures with which it came in contact, particularly the upper and middle lobes of the lung, the peri cardium, and the great veins The cyst extended from the apex of the chest to the diaphragm, and passed across the midline beyond the aortic arch

[1] Willis, R A Teratomas In Atlas of Tumour Pathology Armed Forces Institute of Pathology 1951 Section III F 9 p 7
[2] Colcock, B P Sass P F Staudinger L New Engl J Med 1955 252 371
[3] Hanten, S J Keyes T F Meyer P P *Radiology*, 1955 64 348

The vascular pedicle came from the vicinity of the left innominate vein, and the veins in the pedicle were almost as large as a man's little finger The tumour was lobulated, soft, and thin walled, and contained some solid nodules about the size of chestnuts from which long fair hairs were sprouting The cyst contained sebaceous material which was not infected Histologically it was a benign cystic teratoma

Convalescence was uninterrupted, and on discharge on May 18 he was well and radiographs of his chest were very satisfactory The patient is now very well and is playing tennis and swimming

The interesting feature of this case is the rapid growth of a presumably congenital tumour during two and a half years of adult life

ANTIDIURETIC HORMONE AND SERUM OSMOLARITY IN LIVER CIRRHOSIS

SIR,—According to present knowledge, the liver is the most important site of inactivation of the antidiuretic hormone (A D H)[1] It has been assumed, therefore, that the oliguria and water-retention of advanced liver cirrhosis are partly due to impaired A D H inactivation in the diseased liver Many investigators have found abnormally large amounts of antidiuretic substances in the urine in liver cirrhosis with ascites, but others deny that there is such an increase Stein et al [2] could find no increase in antidiuretic activity in the plasma in liver cirrhosis The A D H bio assays in rats have not been sufficiently accurate, sensitive, or specific,[3] so that the importance of A D H in the pathogenesis of the ascites in liver cirrhosis has not been clarified

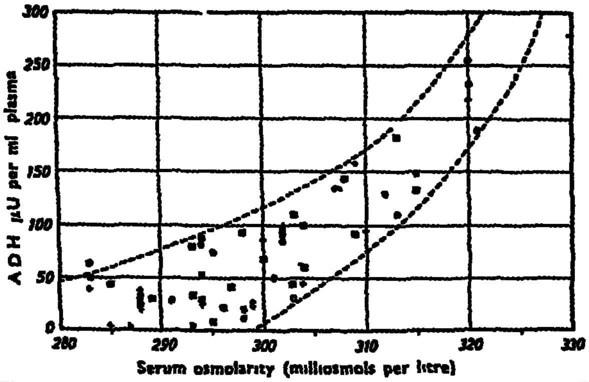

Fig 1—Plasma-A D H level and serum osmolarity in liver cirrhosis (■) and heart failure (●), and in normal adults (+)

Verney [4] demonstrated a relationship between serum osmolarity and diuresis, and it is assumed that hypo thalamic osmoreceptors control A D H secretion from the posterior pituitary We have therefore studied the relationship between serum osmolarity, cryoscopically measured, and antidiuretic plasma activity by a highly sensitive and specific bio assay of A D H on the toad *Bufo vulgaris* [5] This method is sensitive to 10–1000 µU per ml of plasma

There is a highly significant correlation ($P<0.001$) between plasma-A D H level and serum osmolarity (fig 1), which is independent of the nature of the disease, there is no difference between the findings in normal adults, patients with liver cirrhosis with and without ascites, and patients with heart-disease with and without water-retention No correlation was found with the degree of ascites or œdema formation

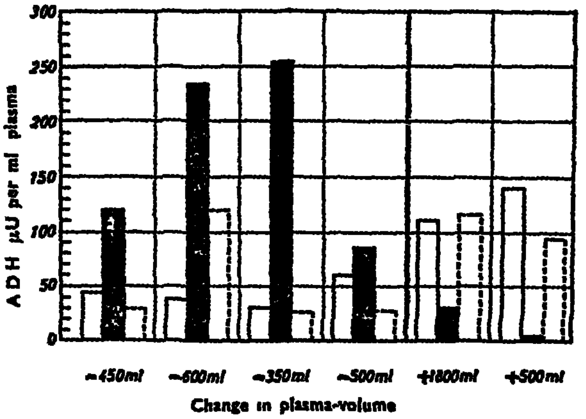

Fig 2—Plasma-A D H level and plasma-volume changes before and after paracentesis in 6 cases of liver cirrhosis, and levels expected from serum osmolarity ☐ Before paracentesis ■ After paracentesis ⌐ Change expected from serum osmolarity

Thus in liver cirrhosis and in congestive heart-failure, it seems that the discharge of A D H from the posterior pituitary is determined by the serum osmolarity and not by factors specific for the disease Delayed A D H inactivation by the diseased liver is also unlikely, since the balance between A D H release from the posterior pituitary and A D H inactivation in this disease is normal Thus in our opinion excessive liberation or persistence of A D H is not an important cause of water retention in diseases with ascites or œdema

There is, however, an exception to this correlation, in long-lasting plasma volume changes after paracentesis for ascites If the plasma volume is decreasing, the plasma A D H level increases considerably above that expected from the serum osmolarity In contrast, an increase in plasma volume causes a decrease of plasma A D H below the level expected from the serum osmolarity (fig 2) Under these circumstances the A D H secretion is, therefore, regulated not only by the serum osmolarity but also by the plasma volume [6–8] The inhibition of diuresis provides a quick replacement of plasma-volume Otherwise, in normal adults, in liver cirrhosis, and in congestive heart failure, water retention follows A D H production, which is stimulated by sodium retention

This work, which was supported by a grant from Deutsche Forschungsgemeinschaft, was published at length in *Klinische Wochenschrift* [9]

TREATMENT OF A DIABETIC DOG

SIR,—Memories of an unhappy Christmas Day vainly spent in trying to rescue my fox-terrier bitch from hypoglycæmic coma prompt me to warn Dr Howick Smith (May 18) that his canine patient may yet prove as fickle as some human ones

Judy, aged 10, developed severe diabetes with ketosis in the late summer of 1955 I started insulin therapy cautiously towards the end of October, and by December she was sugar free on a daily dose of insulin zinc suspension (lente) of 80 units and *no dietary restriction* Her weight rose from 19 lb to $24^1/_2$ lb and she enjoyed long rambles in the Surrey woods

Unlike Dr Howick Smith's dog, she was used to only one meal a day and this was in the evening This was her undoing because though she invariably ate her meal after the injection, she did not do so on Christmas Eve I made the mistake of leaving her unattended, confident that instinct would provide the necessary stimulus to eat her meal

COSTING IN THE CHEMOTHERAPY OF PULMONARY TUBERCULOSIS

SIR,—More patients are now encountered with tubercle bacilli which are resistant to one or more of the commonly used antituberculous drugs—that is, streptomycin *p* aminosalicylic acid (P A S), and isoniazid The following figures are based on a random sample of the patients now under treatment at this hospital

	No of patients
Total	177
Negative cultures since admission	73
Awaiting culture or sensitivity	31
Sputum positive	73
Showing partially or totally resistant strains to one or more drugs (streptomycin, P A S , isoniazid)	37
Percentage of *sputum positive* showing resistance	51

These are patients who for the most part have had chemotherapy before admission In your leading article of April 20, you drew attention to the observation that of 974 positive sputa obtained from newly diagnosed and untreated patients 5 1% showed resistance to one or more of the above mentioned drugs

Considering the price of "resistance" in terms of *£ s d* , the accompanying table shows the relative costs of treating patients with the various agents in use at this hospital, and is based on prices to hospitals, which are lower than those charged when the drugs are prescribed on form E C 10 It is evident that the drugs which we are now sometimes forced to use are very much more costly than the régimes in force hitherto It may be calculated that the cost of maintaining 1 patient for three months on a combination of viomycin and oxytetracycline is some £152 10*s* greater than the cost of streptomycin and P A S Thus in a hospital with a yearly average of, say, 10 patients on this régime the annual difference in cost would be £6100

Drug	Daily dose	Daily cost per patient
Streptomycin	1 g	1*s* 6½*d*
Isoniazid	300 mg	1*d*
P A S (mixture)	20 g	7*d*
P A S (cachets)	19 5 g	11*d*
P A S +isoniazid (combined in cachet)	18 g +300 mg	1*s* 3*d*
Viomycin	2 g twice weekly	7*s*
Oxytetracycline	5 g	28*s* 7*d*
Pyrazinamide	2 5 g	5*s*

These figures show that in addition to creating a major problem in treatment, the resistant bacillus may also be responsible for a progressive increase in the hospital's drug bill

TELEVISION AND MEDICINE

LAST week Dr G B Stanford corrected our statement of May 25 that "the first colour television demonstrations of surgery in Great Britain will take place this summer" Messrs Pye Limited, of Cambridge now point out that in 1950 they installed equipment at St Thomas's Hospital for a five week series of operations televised in full colour to audiences which included an international convention of ophthalmic surgeons "This successful demonstration of the value of colour television excited considerable interest and was, in fact, the first time that colour television had been put to such a use in this country

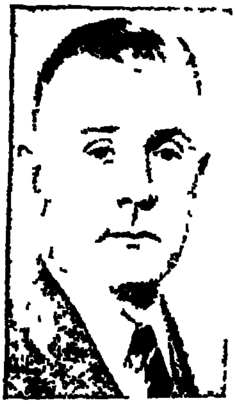
Obituary

ARTHUR GRIFFITH MAITLAND-JONES

O B E , M C , M D Lond , F R C P

Arthur Maitland-Jones will be remembered at the London Hospital as the first director of the children's department, which, especially in its early years, owed much to his clinical wisdom and unfailing kindness

He was born in 1890, the son of the late Rev Joseph Maitland-Jones, and he was educated at Taunton School and the London Hospital Having qualified in 1913, he held house-appointments there before he joined the R A M C on the outbreak of war in 1914 For his services he was twice mentioned in despatches, awarded the Croix de Guerre and the Military Cross, and appointed O B E



On demobilisation he returned to the London Hospital to work as an assistant in the medical unit, and he was associated with Panton and Riddoch in their work on the relation of hæmolytic disorders to pernicious anæmia During these years he took the qualifications for which there had been no time during his war service In 1921 he graduated M B with honours, and in the following year he became M D and M R C P Soon afterwards he was awarded a research fellowship at the Johns Hopkins Hospital in Baltimore, where he worked with Prof John Howland and had opportunity to develop his growing interest in pædiatrics On his return to this country he rejoined the staff of the London Hospital, and in 1924 he became physician in charge of the new children's department He was also appointed to the staff of the Infants Hospital, Westminster, and he was consulting physician to Dr Barnardo's Homes, the Royal Merchant Navy School, and the National Adoption Society He was a valued member of the expert committee of the League of Nations on infant and child nutrition

During the late war Maitland-Jones was hospital sector officer under the Emergency Medical Services and he was also senior hospital officer to Southern Command of the Army These were strenuous years of heavy responsibility, and after his retirement in 1945 he moved to the West Country where he had a farm A year ago he went north to Breconshire But even after he left London he continued to take a benevolent interest in his specialty He had served the British Pædiatric Association as secretary from 1934 to 1943, and in 1949 he was elected president Of his work for the association A A M writes

Arthur Maitland Jones did much to consolidate the pattern and standard of "Windermere" which Donald Paterson had set up Although he was out of sympathy with the change during the war years from what was called a friendly club to the association's concern for 'Medical Politics" (his capitals in a letter to the secretary) he continued to be a regular attender at the annual meetings and was happy in his year of presidency He was always courteous and particularly kind and welcoming to the younger generation who felt confidence in his realistic advice even if they did not always follow it Many will have a lasting memory of his boyishness his friendly smile and eager interest Maitland Jones also did much for the D C H examination to get it started and to see that a satisfactory standard was established He and Leonard Parsons were the first pair of examiners and successors learnt from them and passed on the knowledge of what was intended by this diploma Just after the end of the war he took charge of beds at Great Ormond Street for a period and he admitted in a charming letter at the end of his time there that he too had fallen under the spell of The Hospital for Sick Children which outsiders often regard as a form of arrogance It was typical of him to make this generous confession

Dr Maitland-Jones married in 1928 Miriam, only child of Dr John Ritchey of Oil City, Pennsylvania and she survives him with a son and daughter

EDWIN THOMAS HARRIES DAVIES

M D , M S Lond , F R C S

Mr E T H Davies surgeon to Tredegar Hospital died on May 14 He was a native of Carmarthen and was educated at the local grammar school, the University of Wales, and St Mary's Hospital, London As a student he won many scholarships and prizes at his hospital After qualifying in 1906 he held resident appointments there, and later he became surgical registrar to the London Temperance Hospital In 1908 he took the M.D and in 1910 the M S and F R C S He was the only successful candidate in the M S examination that year

In 1911 he began his work at Tredegar Besides his main hospital appointment he was medical superintendent of the Tredegar Medical Aid Society, medical officer of health for the urban district, and medical superintendent of the infectious-diseases hospital When he retired from his hospital appointment in 1949 a ward was named after him For some years he continued to hold a part-time surgical appointment under the Welsh Regional Hospital Board

I D. writes.

Tredegar was fortunate to secure Edwin Davies s services as surgeon to the former Tredegar Iron and Coal Company and he remained there throughout the whole of his professional life of nearly forty years He was skilled in all branches of surgery, including ophthalmic surgery I met him occasionally in consultation, for I was the visiting physician to his hospital It was soon evident that this densely populated industrial area had received the services of a first class surgeon and he maintained a high hospital standard throughout his working life He was also available for consultations by his colleagues in the town and district His enthusiasm and skill never diminished, and this large community will remember his devoted service and surgical skill.

Mr Davies leaves a widow and a daughter, Dr Caryl St John Davies

Dr HAROLD TRIMBLE

G S T writes

I would regard Harold Trimble as an international figure not only for his work on diseases of the chest but also for the way in which he fostered friendship between the medical profession of America and England He travelled widely all over the world his one idea to gain knowledge from others and cement friendship between the medical professions of the countries visited A man with a striking personality to meet him was at once to like him, and this soon grew to affection

He was always searching after new knowledge in his chosen subject of chest disease and even with his busy clinical life found time to be a member of many prominent committees, both on the administrative side of chest organisation and on the research side

Notes and News

WORLD HEALTH ORGANISATION

AT the close of the World Health Assembly on May 24, the president, Dr S H Al-Wahbi of Iraq said he thought there was general agreement that the World Health Organisation was going in the right direction by devoting increasing efforts to the coördination of research in the control or eradication of disease This did not mean that W.H O was withholding assistance to projects for the control of disease in the field , for example, malaria had been eradicated in 10 countries or territories eradication was under way in 15, and had been initiated or planned in 38 The total population of these 63 countries, the president remarked, was 1211 million—almost half the population of the world

The Darling Foundation medal and prize for outstanding achievements in the control of malaria was awarded to Dr Paul F Russell, of the Rockefeller Foundation For his work in social medicine, Dr Marcin Kacprzak, of Poland, was awarded the Leon Bernard Foundation prize

On May 28 the executive board of W H O concluded a two day meeting under the chairmanship of Sir John Charles, chief medical officer of the Ministry of Health Among the technical reports whose publication was authorised were the fifth report of the expert committee on mental health, the third report of the I L O -W H O expert committee on occupational health and the first report of the expert committee on yellow-fever vaccine

APPROVED NAMES FOR DRUGS

THE British Pharmacopœia Commission has issued the following new supplementary list of approved names for drugs

Approved name	*Other names*
Amisometradine	6 Amino 1 methallyl 3 methylpyrimidine 2 4-dione Rolicton
Florantyrone	γ-Fluoranthen 8 yl-γ-oxobutyric acid Zanchol
Halothane	2 Bromo 2-chloro-1 1 1 trifluoroethane Fluothane
Norethandrolone	17α Ethyl 17-hydroxy 19 norandrost 4-en 3-one Nilevar
Pentacynium	4-(2-[N-(5-Cyano-5 5 diphenylpentyl)-N-methylamino]ethyl) morpholine dimetho chloride Presidal
Prochlorperazine	1-[3-(2-Chloro 10 phenothiazinyl)propyl] 4-methylpiperazine Compazine , Stemetil
Tolpronine	1 (1 2 3 6 Tetrahydropyridino) 3 *o* tolyloxypropan 2-ol Proponesin is the hydrochloride

A COURAGEOUS MATRON

Miss MacManus of Guy's has become a legend One of the most eminent nurses of her time, she played a big part in nursing affairs, travelled widely, and contributed much to the shaping of her profession She has written her memoirs,[1] an unusual and welcome action in a profession traditionally reticent about its personal life

She was the daughter of an Irish doctor in Battersea and niece of the Guy s superintendent s wife, Lady Perry, with whom she spent much of her girlhood It was natural, therefore, that she should exchange the Superintendent's House for the Nurses Home, where she qualified in 1912 In the 1914–18 war she was an Army sister serving mainly in France, and the account of her exciting and strenuous experience is the best part of the book After a short spell as matron of the Bristol Royal Infirmary she returned to Guy's and spent the rest of her career as its matron

The book will delight her many friends and admirers In it they may find themselves and certainly many they have known Miss MacManus s memory is capacious and retentive (or else she has very full diaries) and there is much detail In her memories of two wars, however, enjoyment of adventure and hardship has winnowed the chaff, and here the kind resourceful, and courageous woman shows herself in all her quality

---

University College of the West Indies

Students at this college work for the M B , B.S degrees of the University of London At the examinations for these degrees held in Jamaica in April the following were successful

A St J P Jones S E H Brooks G S McLeod

[1] Matron of Guy s By EMILY E P MACMANUS, C B E London Andrew Melrose 1956 Pp 228 25s

University of London

The title of reader in histochemistry has been conferred on Dr A G E Pearse in respect of his post at the Postgraduate Medical School of London

Medical Women's Federation

The first Christine Murrell fellowship has been awarded to Dr Ann Mullins for her research on disability resulting from obesity

Royal Medico-Psychological Association

Child Psychiatry Section —A meeting of this section will be held at 10 A M on Friday, July 5, at the Warneford Hospital, Oxford, when there will be a symposium on the longitudinal study of physique and personality in a group of children at 7 and 11 years The speakers will include Dr R G McInnes and Dr R W Parnell

Institute of Social Psychiatry

A course on the social approach to mental and emotional difficulties will be held from July 26 to 28 at Moor Park College, Farnham, Surrey Lectures will be given by Dr Joshua Bierer, Dr W Schindler, Dr E K Ledermann, Dr Kraupl Taylor, and Dr Paul Senft Further particulars may be had from the Institute, 9, Fellows Road, London, N W 3

Social Security Agreement with Sweden

The reciprocal agreement on social security between the United Kingdom and Sweden came into force on June 1

Under this agreement, British families will qualify for Swedish family allowances as soon as they become civilly registered in Sweden, and British tourists will be entitled to use the Swedish health services while they are in Sweden The agreement covers also the cash benefits provided by the two countries for unemployment sickness, maternity, old age, widowhood, orphanhood, and industrial injury

Index Ophthalmologicus

A new edition of the *Index*, containing a list of ophthalmologists in all parts of the world, will be issued for the 18th International Congress of Ophthalmology, to be held in Brussels in 1958 Any ophthalmologist who is not a member of the Faculty of Ophthalmologists or the Ophthalmological Society of the United Kingdom, and who wishes to have his name included in the list, is asked to write to the hon secretary of the society, 45, Lincoln's Inn Fields, London, W C 2, before July 31, 1957

Psycho-Endocrine Association

This association was formally constituted on May 21 at a meeting of the Psycho-Endocrine Research Group Its objects are to promote the study of the interrelationship between the endocrine system and mental functions, normal and disordered, to apply the knowledge of these principles to psychological medicine, and to provide a forum for the discussion of psycho endocrinological and related knowledge Anyone, at home or abroad, who wishes to apply for membership should write to the hon secretary of the association, St Ebba's Hospital, Epsom, Surrey The annual subscription has been provisionally fixed at 10s

Neurotics Nomine

The first public meeting of this organisation was held in London on April 29 Dr Joshua Bierer, who presided, said that the future of mental health depended more on public opinion than on what takes place in the consulting-room Mr Christopher Mayhew, M P, said that mental illness was the worst kind of illness and in terms of human suffering was Britain's biggest problem today The aims of the N N (Neurotics Nomine) group are

1 To help patients and ex patients to make contact with each other and with people living normal lives

2 To assist the patient to take the first steps towards more social living and readjustment

3 To support each other by meeting at home or talking over the telephone in an emergency

4 To provide a panel available to discuss or answer questions to an audience of general practitioners or members of social services who have contact with psychiatric patients

5 Generally to help remove the stigma and fear that still surrounds mental illness

6 To help the members themselves in their own integration by providing, through these activities opportunities for useful work, social contacts, and self expression

The hon secretary may be addressed at 9, Fellows Road, London, N W 3

British Medical Association

Dain Fund —During 1956-57 the fund has spent £1460 in helping sixteen cases, including three new ones All the children whom the trustees have been helping for some years are making good progress at their schools and universities

Royal College of Nursing

Miss Catherine Hall, S R N, has become general secretary of the college in succession to Miss Frances Goodall, O B E, S R N, who has retired

Institute of Dermatology, London

A semipermanent exhibition, by Dr R H Meara, on the xanthomatoses, will be available at the institute, Lisle Street, W C 2, till June 29

A course is to be held from Sept 16 to 20 for general practitioners, especially those working in dermatological clinics Applications should be sent by July 8 to the dean of the institute

Hospitals' Symphony Orchestra

This orchestra is holding a concert on June 26 in the library of St Mary's Hospital School, London, W 2 Tickets (7*s* 6*d*, 5*s*, and 3*s* 6*d*) can be had from Miss M A Whipp, A M I A, the Secretary, South Western Hospital, Landor Road, Stockwell, S W 9

MECHANICAL FACTORS IN ATHEROSCLEROSIS

J B DUGUID
M.D. Aberd.
PROFESSOR OF PATHOLOGY

W. B ROBERTSON
B Sc, M.B St And
DEMONSTRATOR IN PATHOLOGY

UNIVERSITY OF DURHAM

THE question of diet in atherosclerosis has occupied so much attention in recent years that the mechanical factors recognised by the older writers seem almost to have been forgotten

More than thirty years ago one of us (Duguid 1926) wrote emphasising the importance of taking functional activity into account in interpreting arterial lesions, and suggesting that atheroma (as it was then called) represented a form of mechanical injury brought about by the discordant movements which followed loss of elasticity of the intima Of late we have been concerned with the thrombogenic hypothesis in relation to atherosclerosis, but we have seen nothing to make us wish to modify the mechanical one put forward in 1926 On the contrary, we have found evidence to support it, and are more than ever convinced that there can be no clear understanding of atherosclerosis until the mechanical factors concerned in arterial function are taken into account The mechanical hypothesis and the thrombogenic are complementary and should be considered in conjunction

Functional Activity of Arteries

The mechanical hypothesis is based on the assumption that the aorta and larger arteries dilate and recoil with each pulse beat This, we must admit, has been called in question It has been stated that the arteries, except the aorta, are kept at an even calibre by contraction of their medial muscle Though we do not believe that this view is widely held, we feel that it has to be considered, if only to bring out certain points which have a bearing on the distribution of the lesions

When a volume of blood is expelled from the left ventricle at systole, the aorta must dilate to accommodate it, and so to some extent must its larger branches It is true that as the pulse wave travels towards the periphery it is gradually smoothed out and dissipated by the elastic yielding of the arterial walls, hence in the smaller vessels the stream becomes practically an even flow, but that is one of the points on which the mechanical hypothesis is based It is not in the smaller vessels that atherosclerosis tends to develop but in the aorta and the coronary and other medium-sized arteries which receive most of the impact of ventricular systole The lesions develop mainly at bifurcations, branchings, and flexures where the stream strikes directly against the vessel walls, they are most prominent in arteries which, being loosely supported, are less restricted in movement (e g, the extramural coronaries and the cerebral arteries), they are prevalent in such conditions as hypertension where the pulse pressure is high, and in short they abound wherever and in whatever conditions pulse movements are accentuated

If, as is generally acknowledged, the conversion of the blood-flow from an intermittent to a continuous one depends on the elastic yielding of the arterial walls, then there must be movements of the walls How great these movements are, or how far they are carried towards the periphery, is uncertain, but in so far as they are known to occur they must be regarded as potential sources of strain

Arterial Structure

To understand the possible effects of pulse movements it is necessary to consider certain peculiarities of arterial structure The arteries are elastic tubes composed of at least three different tissues—muscle, elastic tissue, and fibrous tissue Since these differ in their elastic properties, the efficiency of the structures as a whole depends to a great extent on the special arrangement and freedom of interaction of these elements It should be understood that, although muscle predominates in many of the arteries, there is no question of a muscular contraction and relaxation at each pulse beat Muscular contraction is concerned with the tone of the arteries, which determines their mean diameter relative to the blood-pressure, but muscle is also elastic and can therefore be stretched and will recoil again to its original length when the stretching force is removed This is the property which enables the arteries to dilate and recoil with the pulse beats

It is sometimes thought that the elasticity of arteries depends essentially on the so-called elastic tissues they contain, but, judging by the appearance of the elastic laminæ in histological sections, the elasticity of these is not of a very high order In this connection there is a fundamentally important point which is commonly overlooked MacWilliam and Mackie (1908) showed that arteries contract after death, and that the degree of contraction is indicated by the wavyness of their elastic laminæ and the wrinkling of their intimal surfaces This is important in two respects (1) it means that most arteries examined are in a state of post-mortem contraction, a fact which should always be taken into account in interpreting pathological appearances; and (2) it shows that the elastic laminæ cannot shorten to the same extent as the muscle and so have to adjust themselves by folding or wrinkling The same applies to the fibrous tissue of the intima, which is usually finely wrinkled in sections

Since it is obvious that all these tissues have to stretch to the same point when the artery is dilated, it follows that the muscle, which is responsible for the contraction, has a greater range of recoil than either of the other elements—in other words, a greater degree of elasticity This may seem trivial but it is important, not so much as a measure of the elasticity of the various elements as in the fact that it illustrates how the elements adjust themselves to movements beyond their contractile range From it we see that for complete functional efficiency there must be looseness and flexibility of the tissues

Mechanical Hypothesis

The suggestion put forward in 1926 was that impairment of the elasticity or flexibility of the intima of an artery must lead to just that kind of structural disorganisation which is seen in atherosclerosis In that condition there are dense fibrous thickenings which obviously stiffen the intima, and their disruptive effects are brought into prominence by post mortem contraction In the atherosclerotic aorta, for example, the thickened intimal plaques, being too stiff to conform in the normal way to the contraction, become coarsely crumpled, with the result that in parts they bulge into the lumen and are torn away from the media (fig 1) Post mortem contraction, it was suggested, is merely an exaggerated recoil, and the pulse movements in life, although more limited, must have similar effects Accordingly atheroma

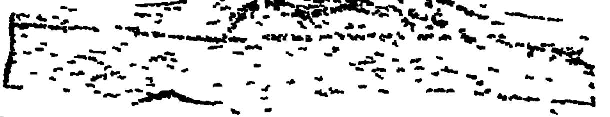

Fig 1—Atherosclerotic plaque in aorta (frozen section) post-mortem contraction has caused the stiffened intima to buckle inwards and become loosened from the media. It is suggested that the same effect is produced by pulse movements in life, and that the spaces so formed becoming filled with fatty debris, constitute atheromatous foci (Hæmalum × 10)

was viewed as the tearing and destruction of tissues which resulted from thickening and loss of elasticity of the intima

This conception was but a slight modification of a view which had long been current, Virchow having regarded atheroma as a loosening of the tissues of the intima Later Aschoff, in Germany, and Sir Clifford Allbutt, in this country, described it as an effect of shearing between the layers, and though all these authorities recognised pulse movements as the damaging forces they ascribed the damage to overdistension of the arteries rather than to the elastic recoil, and imagined a sliding of one coat over another rather than a tearing apart of the layers

The new hypothesis had little appeal since it was based on a post mortem appearance which had no ascertainable relationship to conditions in life Even on the assumption that the arteries moved with pulsation, it could not be claimed that any pulse movement would be comparable with the contraction occurring in an artery when it is emptied of blood, and there seemed to be no way of showing that the elastic recoil in life could ever be forceful enough or extensive enough to injure the tissues in the way suggested The apparent bulging of the intima in atherosclerosis had always been taken for a swelling or proliferation of the tissues together with an accumulation of fat, and in view of this apparently straightforward explanation the crumpling idea seemed a little fanciful Moreover it did not adequately explain the two most important processes in atherosclerosis—fatty change and fibrous thickening Ever since Anitschkow showed that a cholesterol rich diet produced lipoid deposits in the arteries of rabbits, it had been taken for granted that fatty change was the primary and essential one, and no theory which did not explain it was likely to be acceptable

Nevertheless the new hypothesis was of value in that it provided a fresh way of looking at arterial diseases, and one by which many of the old-established notions would not bear scrutiny There was, for example, one important feature of atherosclerosis which was commonly interpreted in a way that could not easily be reconciled with the mechanical point of view—namely, narrowing

It had always been taken for granted that the narrowing of arteries was due to overgrowths of the intimal fibrous tissue encroaching on the lumina, but, when functional activity was taken into account, this seemed very unlikely Arteries are elastic tubes, dilating and recoiling with each pulse beat, and, whereas the dilatation is a movement imposed on them by the pulse pressure, the recoil is a function of their own elasticity, and anything like a fibrous overgrowth which reduces this must interfere with their ability to recoil They will thus be left in the more or less dilated position and, deprived of their elasticity, will be likely to stretch progressively under the influence of the blood-pressure

To those accustomed to the orthodox view this may seem an awkward line of reasoning, but it is largely borne out by the vast majority of atherosclerotic lesions In them the arteries are for the most part wider than normal, and it is only occasionally and in some parts that they are narrowed, but the narrowing, when it occurs, tends to dominate the picture, with the result that it has come to be regarded almost as an essential part of atherosclerosis

Thrombogenic Hypothesis

It was, as we have stated, difficult to see how an overgrowth of the intima could narrow an artery, but the fact remained that the arteries were in some instances narrowed, and it seemed that some explanation other than an overgrowth was to be found One could imagine various ways in which the lumen of an elastic tube could be reduced, the simplest being by partially occluding it by solid matter, which was exactly what happened when a mural thrombus formed in an artery, but in the early part of this century arterial thrombosis, apart from total occlusion, was not regarded as very common, and it did not therefore suggest itself as a likely solution to this problem Nevertheless a search was made in cases of coronary and aortic atherosclerosis for evidence of mural thrombosis, and the results were surprising (Duguid 1946, 1948) Thrombi of all kinds were found with astonishing frequency, ranging from large masses of red clot, almost occluding the lumina of the arteries, down to thin mural deposits of fibrin, so small as to be hardly detectable Some were freshly formed and others partly organised, and from a comparison of the various examples it soon became evident that thrombosis, instead of being an occasional complication of atherosclerosis, was an important factor in its pathogenesis

When a mural thrombus forms in an artery it becomes covered with endothelium and is incorporated in the vessel wall, with the result that, on subsequently being organised, it forms a fibrous thickening of the intima The endothelium is in fact an adjustable membrane (Duguid 1952) capable of rearranging itself so as always to interpose a cellular lining between solid matter and the blood-stream, and by this mechanism tissues which form part of a vessel wall may actually have originated as hæmatogenous deposits in the lumen Mural thrombi, especially if they are of the red type, commonly undergo fatty change and thus assume the characters of atherosclerotic plaques, and there is good reason to believe that a considerable proportion of the lesions classified as atherosclerosis are altered thrombi

The thrombogenic hypothesis has been confirmed by a number of observers, including Harrison (1948), Geiringer (1951), Heard (1952), Crawford and Levene (1952), Morgan (1956), and others, and thus, out of the application of the mechanical hypothesis, the long forgotten teaching of Rokitansky was revived and a new principle in arterial pathology established in the light of which much of arterial pathology needs to be reconsidered

It is therefore easy to see how narrowing of the arteries is brought about, and it may seem surprising, in view of the frequency of mural thrombosis, that narrowing is not more constant But there is, as we shall show, a compensating mechanism whereby that danger is usually averted

Effects of Mural Thrombosis

There can be no doubt that the incorporation of a mural thrombus into the intima of an artery reduces both the elasticity and the flexibility of that coat Mural thrombi, when newly formed, may be relatively soft and plastic, but under the influence of the pulse pressure they are soon beaten into compact layers of hyaline substance, and when they are converted into fibrous masses they affect the vessels in various ways according to their relative size In the first place, quite apart from their occluding effects, they may, if large and firm, practically immobilise the particular segments of the vessel walls to which they are attached, and, when they do so, the walls are fixed nearly always in the dilated position

To understand this fundamental point it is necessary to remember that the thrombi, if they leave enough room for an effective blood stream to pass, immediately come under the influence of the blood-pressure and have to conform to such movements as it imposes They have to accommodate themselves to the shape of the vessel wall at the height of the pulse wave, and, being more plastic than resilient, they become moulded to that shape, so that when they are subsequently converted into fibrous tissue they may, if firm, virtually clamp the vessel wall in the dilated position Thus mural thrombi, although they at first reduce the lumina of the arteries, tend to increase their mean diameter, thus cancelling out the initial narrowing, if it is not too great When this effect is coupled with the progressive dilatation which follows loss of elasticity, the compensation may be more than adequate. Consequently atherosclerotic arteries, even when greatly thickened, are often wider than normal—the "senile ectasis" of Aschoff (1937)—and it is only when relatively large thrombi form in small vessels that there is absolute and permanent narrowing.

Smaller thrombi, on the other hand, have a more localised effect; and this, we believe, is what constitutes the atherosclerotic process. A thrombus may be too small to interfere with the resilience of the vessel wall, but if it cannot move in unison with the rest of the structures it is bound to create local discord, and, if movements continue in spite of it, something has to give way. In the contracted artery post mortem we have seen what may happen, but it remains to be shown that the same happens in the living artery, and it is in this connection that intimal hæmorrhage is significant.

Fig. 2—Atherosclerotic plaques in aorta, showing thickened intima coarsely crumpled and in parts loosened from media. Dark patches at angles of separation represent hæmorrhages. (Direct photograph × 10.)

Intimal Hæmorrhage

The transformation of mural thrombi into fibrous thickenings has been adequately described elsewhere, but there is one feature to which we must draw special attention because it concerns the evidence we present. Where large thrombi are concerned, a full-scale process of organisation is established, such as is seen in a fibrinous exudate. Capillaries enter from the lumen of the vessel and from the vasa vasorum (Geiringer 1951, McLetchie 1952) and invade the mass, vascularising the intima. Since many of these new vessels remain after the organisation is completed, they become a feature of advanced atherosclerosis. Such vessels may be a source of hæmorrhage, and it is in this we find the evidence of mechanical effects.

Intimal hæmorrhage has long been recognised as a feature of atherosclerosis, but special attention has been paid to it in recent years, chiefly as a result of the detailed studies by Winternitz et al. (1938), Paterson (1938), and Wartman (1938). It is perhaps unfortunate that some of the most conspicuous examples are seen in cases of fatal coronary thrombosis, and that more attention has been paid to these, and their possible relationship to coronary occlusion, than to the small and inconspicuous extravasations of blood which are far commoner and in our opinion no less significant.

These small extravasations are usually seen in the deeper layers of the intima and quite unconnected with the surface, so there is no reason to suppose that they play any part in fatal occlusion. They often consist of no more than a few erythrocytes lying free in the tissues, and where there is much fatty change they are easily overlooked. Winternitz et al. noted that they were often situated at the margins of the atheromatous foci, but they related this to the fact that vascularisation was plentiful in these areas, and, beyond remarking that mechanical factors might play a part in their production, they did not connect them with injury. Nevertheless these extravasations occur just at the points where the layers of the intima are apparently being torn apart, and their presence seems fairly clear proof that the tearing has occurred in life.

Our attention was first drawn to this in a common iliac artery excised surgically because it was occluded. The intima in this vessel was greatly thickened by several layers of fibrous tissue, one of which was fractured. The fracture might have passed as an artefact, caused by rough handling, had there not been signs of old hæmorrhage around it, showing that it had taken place some time before the vessel was excised.

This observation led us to look for other evidence of the same kind, and one of the first coronary arteries to be examined with this in mind provided it. In this vessel there was a patch of thickened intima canted upwards and thrust into the lumen, so that it was almost severed from the neighbouring part, and again there was antemortem hæmorrhage at the point of tearing.

Of 50 cases of severe coronary atherosclerosis, not all with fatal occlusion, we found hæmorrhages in 33. These hæmorrhages were typical examples of a condition with which we had long been familiar, but it was not till we came to study their exact situation that their significance became apparent. In 16 of them they were almost all at the margins of the atheromatous foci, just at the points where the layers of the intima were being torn apart, and even in the other 17, where the extravasations were more widespread, there were usually some points of leakage in these same situations.

This feature is most easily demonstrated in the aorta. For example, fig. 2 shows a patch of thickened intima coarsely crumpled and partially torn away from the media in several places, the dark patches at the angles of separation are hæmorrhages. This finding, which is by no means uncommon, seems to provide the strongest support for the mechanical hypothesis, for it indicates, as clearly as any histological sign could, that the same forces as tear the layers of the intima apart in post-mortem contraction are also in operation in life and are a source of injury to living tissues.

Hæmorrhage and Atheromatous Degeneration

One of the deficiencies of the mechanical hypothesis as put forward earlier in this paper was the fact that it did not explain the fatty changes in atherosclerosis. It was subsequently noted incidentally that mural thrombi themselves undergo fatty changes, but it was not suggested that all the fatty debris which accumulates in atherosclerosis is derived from thrombi. The debris is altogether too plentiful, and the accumulations occur in the deeper layers of the intima, beneath the thrombi, rather than in them, so obviously there must be some other sources of the fat. The view we now wish to bring forward was prompted mainly by a demonstration by Dr A. D. Morgan to the Pathological Society of Great Britain and Ireland in January, 1956.

Morgan recalled that Winternitz et al. in 1938 had suggested that atheromatous material was derived from intimal hæmorrhage, but it was his own demonstration that convinced us of the truth of this and showed how the thrombogenic hypothesis could be linked with the mechanical one. In his monograph on *The Pathogenesis of Coronary Occlusion*, Morgan (1956) concludes that the cholesterol and other fatty debris in atherosclerosis are products of blood destruction and can be accounted for by small hæmorrhages recurring over long periods. Our own findings confirm this. The hæmorrhages almost always communicate with the atheromatous foci, and disintegrating corpuscles are usually so intimately mixed with lipoid droplets, cholesterol crystals, hæmosiderin, ceroid pigments, and other debris that it is hard to avoid the conclusion that the larger atheromatous accumulations are the products of recurring hæmorrhages.

It would hardly seem prudent at this stage to suggest that all the fatty changes in atherosclerosis could be products of hæmorrhages or thrombi, since neither hæmorrhages nor thrombi are detectable in most of the early lesions. Yet Paterson et al. (1956) have reported that iron pigment is demonstrable even in the very early fatty lesions, and we have been able to confirm this. Since blood is the most likely source of such pigment, we are forced to conclude that intimal hæmorrhage must be commoner than is generally supposed. It is perhaps difficult to accept the idea of hæmorrhage where there is no vascularisation of the intima, but it should be recognised that, in the arterial walls, there are peculiar physical conditions making the introduction of blood into the intima possible without vascularisation, especially when there is no great thickening.

Many writers have discussed the question of tissue pressure in relation to permeation of the arterial walls by fluids and hæmorrhage (Drury 1954), but few have taken into account how pressure may be affected by pathological processes. In the normal artery the intimal tissues are constantly under a positive pressure which varies with pulsation, but the same conditions do not necessarily obtain in the atherosclerotic artery. When, during recoil, the thickened intima is crumpled and loosened from the media, there must be phases of reduced pressure at the points of loosening, with the result that fluids are drawn in to fill the spaces thus formed. The most readily available fluids are blood and plasma, and the fact that fats are found need not be surprising in view of the fact that these fluids may be rich in lipids. It seems hardly necessary, therefore, to postulate disturbances of the lipid metabolism, or specific affinities on the part of the arterial tissues for lipids, to explain the presence of these substances in the arterial walls.

Experimental Evidence of Mechanical Factors

In 1933 Harrison recorded some experiments which seem never to have received due attention. He produced cholesterol lesions in rabbits previously treated with large doses of calciferol to produce medial calcification of their aortas. Whole segments of their aortic walls were rigidly calcified; and, when the affected rabbits were later given the standard cholesterol treatment, only the parts of their aortas which still remained mobile developed cholesterol deposits, while the rigid parts remained free. The only exceptions were one or two instances where the rigid layers had fractured and presumably injured the overlying intima, which was heavily infiltrated with cholesterol at these points. In most of the cases, however, the greatest depositions were immediately around the margins of the calcified areas, where local discord was likely to have been most acute.

If there is anything to be learned from experiments on animals regarding the cause of atherosclerosis, surely it is that movement is the crucial factor. Cholesterol experiments have repeatedly been cited as evidence that fats are the prime factors in atherosclerosis, but Harrison's experiments *show that cholesterol is merely a very* effective "marker" of structural damage which is otherwise obscure. Aschoff (1924) stated that: "The lipoid concentration of the food does not cause atheroma, but essentially influences the characters of the atheromatous patches by determining the presence or absence of fatty change," and Harrison's experiments seem to bear this out.

We have also seen this borne out in the recent case of a coloured Jamaican who died of carcinoma of the liver. He was so emaciated that even the atheromatous fats in the aorta and coronary arteries were replaced by a gelatinous substance. The arteries were in no way improved by this, however, for there was still the same structural disorganisation. There was, in fact, still the same degree of atherosclerosis, but the character of the atheromatous patches was influenced by a shortage of fats.

The Genesis of Atherosclerosis

It has been shown how mural thrombosis leads to atherosclerosis, but little has been said about the cause of the thrombosis itself. The factor commonly cited is damage to the vessel walls, and the findings in atherosclerosis bear it out, since most of the recognisable thrombi in that condition are associated with lesions of the underlying intima. Atherosclerosis is itself a form of damage and tends to promote further thrombosis; so the typical plaque is often built up of successive fibrin deposits, one on top of another in a laminated formation; but how the process begins in the first place is a more difficult problem.

There are many conceivable ways in which the internal lining of an artery may be damaged, and to cite any one as the primary lesion in atherosclerosis can only be speculative. Atherosclerosis begins in childhood (Geringer 1948), and in the arteries in children it is often difficult to distinguish normal changes from pathological ones. In man there is a progressive fibrous thickening of the intima of the larger arteries almost from birth, and so universal is this that it can be taken as a natural growth process. One might therefore hesitate to compare it with atherosclerotic thickening, yet Levene (1955) has found that, even in the aorta of young children, the subendothelial layers contain fibres which in their electron microscopic pattern resemble fibrin. If his findings are confirmed, we may have to conclude that in normal development, as well as in atherosclerosis, the intima is increased by the incorporation of solid matter from the blood stream.

We are accustomed to thinking of normal growth processes as beneficial, and we assume that, so long as these natural thickenings of the intima are even and uniform, harmony would be maintained; but in point of fact they seldom are uniform. Even in young children the intima of the aorta around the openings of the intercostal arteries is usually thicker than elsewhere, and it is perhaps significant that these are the sites of the earliest fatty streaking in young people as well as of some of the severest lesions in adults. It seems likely that even the slightest local overloading of the intima with fibrous tissue may interfere with coordination of the structures, and, although in ordinary circumstances a slight stiffening may be tolerable, it must nevertheless reduce the ability of the tissues to adapt themselves to any increased vascular activity that may arise. Thus even in our natural growth processes there may be the potentialities of disease.

Dangers of Atherosclerosis

We are therefore forced back to the position of the older writers who regarded atheroma as part of the wear and tear of life, and this, in view of the increasing incidence of deaths from coronary disease, may seem alarming. It need not unduly disturb us, however, for coronary disease is not quite the same as atherosclerosis. "Coronary disease" is a clinical term implying narrowing or occlusion of the coronary arteries, and narrowing is not an essential part of atherosclerosis. There can be severe atherosclerosis of the coronary arteries, for instance, without any narrowing, just as there can be fatal narrowing without much atherosclerosis. Hence the death-rate from coronary disease in a community is no reliable gauge of the prevalence of atherosclerosis.

This may seem paradoxical in view of our contention that atherosclerosis and arterial narrowing are both products of thrombosis, but it must be appreciated that thrombosis is a double-edged process. It may on the one hand be part of a natural protective or reparative mechanism, or it may on the other be a dangerous pathological process; and the thrombi which are responsible for atherosclerosis may be quite different in their nature from those which cause occlusion. Atherosclerosis is universal in adults, and all adults have thrombosis in their coronary arteries from time to time, but so long as the thrombi are small no great harm is done There are factors in the blood or in the tissues which control thrombosis and keep it within safe limits, and it is when such factors fail that the process gets out of control and becomes a danger That state of affairs is a complication of atherosclerosis rather than an essential part of it

It is beyond our present scope to discuss the factors which govern thrombosis Astrup (1956) has referred to the multiplicity of agents, activating and inhibiting, which maintain the equilibrium between the formation and removal of fibrin in the living body, and in summarising them has made a strong case for regarding fibrinolysins as the critical factors Mole (1948) has made similar suggestions and it seems clear that fibrinolysins are among the first problems to be tackled in the campaign against coronary disease

Uncomplicated, or simple atherosclerosis (if we may use the term), is a very different problem Although thrombosis plays a part in its development, it is a relatively benign part, and if we are to treat the condition as an evil whose cause must be eliminated we have far fields to explore in seeking the cause In the past thirty years medical thought has tended to veer away from the idea of wear and tear and to ignore mechanical factors, perhaps because these factors have been rather vaguely represented, but it is doubtful if any worker in this field would entirely rule them out For our part, we have repeatedly asked ourselves what must happen when a layer of relatively inelastic material is fixed to the inner surface of a pulsating elastic tube, and the answer has always been something which in its general configuration would reproduce very closely what is found in atherosclerosis

(*concluded from p 1161*)

LONG-TERM PROGNOSIS

WE have already shown that, of 543 patients with myocardial infarction admitted to the Radcliffe Infirmary in 1940–54 195 died within eight weeks—a period arbitrarily selected as covering the acute attack Thus there were 348 survivors of the acute attack We review here the prognostic factors influencing the course of these survivors

TABLE XXX—NUMBER OF DEATHS IN REMAINDER OF THE FIRST YEAR IN DIFFERENT TREATMENT-PERIODS

Period	No surviving acute attack	Deaths in remainder of first year	
		No	%
I (1940–47)	66	10	15 2
II (1948–51)	105	14	13 3
III (1952–54)	177	25	14 1
Total	348	49	14 1

TABLE XXXI—DEATHS AMONG SURVIVORS OF THE ACUTE ATTACK IN REMAINDER OF THE FIRST YEAR

Sex	Good risk			Bad-risk		
	No of patients	Deaths		No of patients	Deaths	
		No	%		No	%
Male	127	7	5 5	110	26	23 6
Female	50	3	6 0	61	13	21 3
Total	177	10	5 6	171	39	22 8

Findings

Prognosis during the Remainder of the First Year

The chance of dying during the remaining ten months of the first year was still considerable. 49 patients (1 in every 7) died in this period The majority of these 49 deaths were in the earlier months after the acute attack—33 in the first four months In other words, about 10% of the survivors of the acute attack died during the succeeding four months During the period covered by our study (1940–54), there has been no improvement in this respect (table XXX)

Some individual factors are of considerable importance in determining prognosis during this first year We have confined ourselves to clinical factors which can be recognised early in the course of the acute attack From our own data the important factors associated with a bad prognosis in patients who survive the acute attack are

TABLE XXXII—DEATHS AMONG TWO MAIN AGE GROUPS IN REMAINDER OF FIRST YEAR

Age (yr)	Good risk			Bad risk		
	No of patients	Deaths		No of patients	Deaths	
		No	%		No	%
Under 60	100	5	5 0	63	12	19 0
Over 60	77	5	6 5	108	27	25 0

(*a*) Evidence of cardiac distress in the early days of the acute attack (1) cardiac failure, either left ventricular or congestive, and not necessarily severe, (2) cardiac arrhythmia (auricular fibrillation or flutter, or multiple extrasystoles), or (3) gross cardiomegaly

(*b*) A history of a previous attack of myocardial infarction, though this is less important than the factors covered in (*a*)

Factors which seemed to have little bearing on prognosis in this stage included known hypertension, diabetes mellitus, and previous angina of effort We can therefore divide the survivors of the acute attack into good risk and bad risk cases, the bad-risk ones being those with cardiac distress early in the acute attack or whose recent infarction was not their first During the remainder of the first year the bad-risk patients are four times as likely to die as the good-risk patients (table XXXI) As in the acute attack, sex did not influence the prognosis

Age has negligible importance in prognosis compared with whether the patient is a good or bad risk as already defined As individual age groups are small, we have fused them into two main age groups (table xxxii, fig 11)

Among the good-risk patients the development of another myocardial infarct was the major cause of death Among the bad-risk patients, death from recurrence was commoner than among the good-risk patients, but death from cardiac failure unassociated with a fresh infarct was the outstanding cause of the difference between the two groups (table xxxiii)

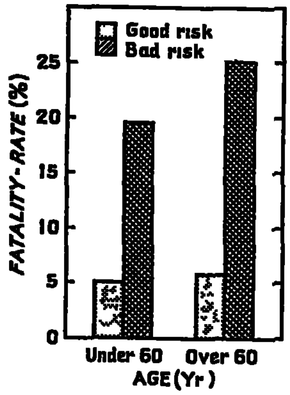

Fig 11—Fatality rates two to twelve months after myocardial infarction in good risk and bad-risk patients aged under 60 and over 60

Prognosis over Several Years

The fatality-rate in the second year after an infarct was lower than in the first year but still considerable, 1 in every 10 patients died in this period Thereafter, the fatality-rate ran at a lower level Allowing for random fluctuations, about 5% of the survivors of the original acute attack died each year after the second year (table xxxiv, fig 12) It will be recalled that, though all but 1 of the patients were followed up to January, 1956, the length of follow-up varied, and therefore the number of patients shown as followed up dwindles progressively over the years We have included a cumulative fatality rate because this gives a good overall picture of the subsequent fate of the survivors of the acute attack Of every 5 survivors of the acute attack 2 died within five years, and by ten years the proportion had risen to 2 out of every 3 The population at risk contained many old people, however, and a considerable number of deaths would be expected in any event The Registrar-General (1956) has given the survivorship ratio for each age group of men and women over the course of five years, 1946–50—a period which falls conveniently in the middle of the time covered by the present study We have taken these figures to estimate expected fatality-rates for the survivors of the acute attack Over five years the fatality rate among the survivors of the acute attack of myocardial infarction was 39 3%, the corresponding figure for a sample of the same age and sex composition, but taken from the general population, was 16 1%—i e, the chance of dying within the next five years was $2^1/_2$ times as great for survivors of myocardial infarction as for persons of the same age and sex in the general population

TABLE XXXIII—CAUSES OF DEATH IN REMAINDER OF FIRST YEAR

Cause of death	Good risk (177 patients)	Bad risk (171 patients)
Recurrent infarction	7 (*4 0*%)	13 (*7 6*%)
Cardiac failure unassociated with recurrent infarction	3 (*1 7*%)	19 (*11 1*%)
Other known causes	0	3 (*1 7*%)
Uncertain	0	4 (*2 3*%)*

* In some of these patients there was presumptive evidence of cardiac failure

TABLE XXXIV—PROGNOSIS OF SURVIVORS OF ACUTE ATTACK

Period of follow up	No of patients followed	Deaths in corresponding period		Cumulative fatality rate (%)
		No	%	
Remainder of 1st year	348	49	14 1	14 1
2nd year	292	29	9 9	24 0
3rd year	236	15	6 4	30 4
4th year	179	8	4 5	34 9
5th year	137	6	4 4	39 3

Long-term Prognosis of Good risk and Bad-risk Patients

We have already defined the factors influencing death in the first year, and it is interesting to see for how long these factors operate The bad-risk patients were four times as liable to die in the first year as the good risk patients and twice as liable to die during the second year, but thereafter the two groups had a similar risk of dying (table xxxv) After five years, three-quarters of the good risk patients and half the bad risk patients were alive Another way of looking at the same information is to compare the expectation of living five years for the good-risk and bad risk patients with that of samples of the general population of the same age and sex A good risk patient had less than twice an "average man's" chance of dying, while a bad-risk patient had more than three times this chance (table xxxvi, fig 13)

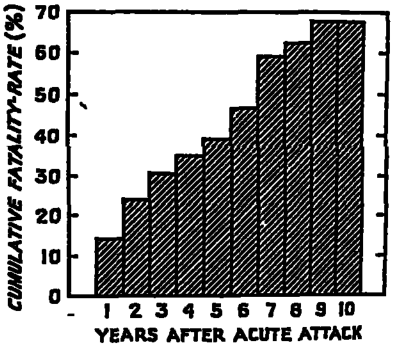

Fig 12—Cumulative fatality rate among survivors of acute attack

Prognosis in the five years after the acute attack depended on the age of the patient as well as on whether he was a good or bad risk Good-risk patients did better than bad risk patients in both age groups (table xxxvii), but the good-risk patients over the age of 60 years fared better than the corresponding patients under the age of 60 (fig 14) The chance of death in the patients over 60 in the good-risk group was about the same as that of the general population In the under 60s, the survivors of a myocardial infarction had more than three times the normal expectation of dying within the next five years Fatality-rates in the bad-risk patients were greatly above the "expected" levels in both younger and older patients, but the outlook in the younger age groups (though better in absolute figures than that in the older age groups) was worse when considered in relation to normal expectation

TABLE XXXV—SURVIVORS OF ACUTE ATTACK SEPARATELY FOR GOOD RISK AND BAD RISK CASES

Length of follow up (yr)	Good risk				Bad risk			
	No of patients	Deaths		Cumulative death rate (%)	No of patients	Deaths		Cumulative death rate (%)
		No	%			No	%	
1	173	10	5 8	5 8	175	39	22 3	22 3
2	146	9	6 2	12 0	146	20	13 7	36 0
3	117	7	6 0	18 0	119	8	6 7	42 7
4	83	4	4 8	22 8	96	4	4 2	46 9
5	61	3	4 9	27 7	76	3	3 9	50 8

In view of these findings, it is of great interest to know the causes of death in the various groups In most of the patients who died, we know fairly precisely the course of events, though there is a minority for whom the information is inadequate Our main concern was

TABLE XXXVI—PERCENTAGE FATALITY-RATE OVER FIVE YEARS IN GOOD-RISK AND BAD-RISK GROUPS COMPARED WITH EXPECTED RATE IN GENERAL POPULATION OF SAME AGE AND SEX

—	Good-risk group	Bad-risk group
Survivors of myocardial infarction	27·7	50·8
General population	15·3	15·2

to see whether death followed a recurrent infarction or whether it was due to cardiac failure without clinical evidence of fresh infarction.

The relatively bad prognosis in the good-risk patients under 60 years was almost entirely due to recurrent infarction (table XXXVIII). Among the bad-risk patients, the chance of dying from recurrent infarction was about the same as for the *good-risk* patients under 60, but in addition there were many deaths from cardiac failure not due to a fresh infarction, and it was the combination of these two risks which made their outlook poor. The small number of deaths following recurrent infarction in the older good-risk patients seems the chief reason for their favourable prognosis.

Long-term Prognosis from Time of Admission to Hospital

We can now see the total prognosis of patients admitted to this hospital in the past fifteen years (table XXXIX, fig. 15). In simple terms, 1 patient in every 7 admitted died in the first forty-eight hours, and a third were dead by the end of the eighth week (which we have taken as concluding the acute attack). By the end of two years from admission, half the original patients were dead. Thereafter, the risk of dying diminished, but another 10% died in the next three years, and by the end of five years 3 out of every 5 patients admitted were dead. The fatality was therefore formidable. But the risk of death was not evenly distributed, and the correct recognition of good and bad prognostic features makes it possible to select patients who, provided they survive the acute attack, have an expectation of life similar to that of persons of a corresponding age in the general population.

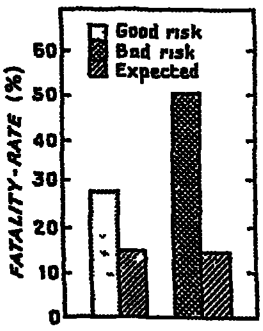

Fig. 13—Fatality-rate over five years in good-risk and bad-risk cases compared with expected rate in general population of like sex and age composition.

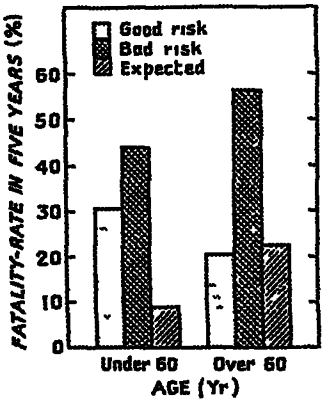

Fig. 14—Proportion of survivors of acute attack who die in next five years, compared with expected figures.

Discussion

Various studies have been made in the past twenty years of the long-term prognosis of myocardial infarction. Before that time, though it was realised that some patients could survive for many years, these were regarded as exceptional.

TABLE XXXVIII—MODE OF DEATH IN THE FIVE YEARS AFTER MYOCARDIAL INFARCTION IN VARIOUS GROUPS

—	Good-risk		Bad risk	
	Under 60	Over 60	Under 60	Over 60
Mode of death

Other known causes	1	0	3	3
Uncertain	4	2	2	8
No. of patient/years of follow-up	346	254	222	370
Rate of recurrent infarction taking good risk <60 as 100	100	45	114	106

In 1934, a meeting of the Royal Society of Medicine concluded that there was insufficient evidence for any assessment of the long-term prognosis (Hay 1934).

Palmer (1937) analysed the records of patients known to have survived a coronary thrombosis and found almost 75% alive at the end of five years; unfortunately 45% of the patients could not be traced, so this estimate was subject to gross error.

Bland and White (1941) found that 31% of those who survived the acute attack were alive ten years later, but their study is open to the grave criticism that they included patients in whom coronary occlusion had been diagnosed retrospectively; naturally, such patients would bias the results in a favourable direction.

Katz et al. (1949) made a better study with a 97% follow-up lasting one to five years. Their results bear some resemblance to our own, except that their patients showed a generally worse prognosis. In their study, there was a very heavy incidence of recurrent infarction.

The present study has the advantage of being virtually 100% complete. There is the limitation that the period of follow-up varies from one to sixteen years, but we have been encouraged to treat the group as homogeneous because the proportion of patients dying in the first year

of follow up has been remarkably constant throughout the total period covered by the study This being so, simple actuarial procedures allow us to make use of the whole series to estimate survival-rates Long-term anticoagulant therapy was used in so few patients that it can be ignored, and the present results therefore represent the survival of patients in an era before long term anticoagulant therapy was in vogue

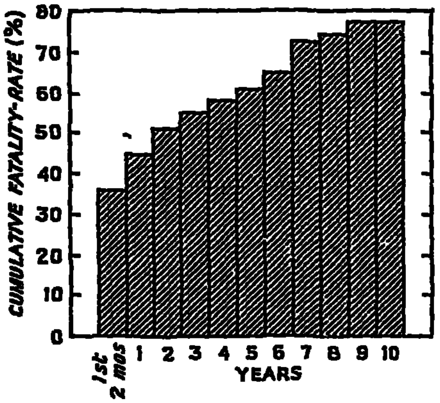

Fig 15—Prognosis from time of admission to hospital to ten years later

With respect to the individual factors which make for a good or a bad long-term prognosis, our results are definite The importance of recurrent infarction emerges from this as from other studies The only subgroup which is relatively free from this hazard is that composed of good-risk patients over the age of 60 years These patients have the same chance of living five years after the acute attack as individuals of the same age and sex in the general population From the point of view of future preventive treatment, the high rate of recurrence among good-risk patients under 60 is especially important It is this risk alone that causes them to have a much greater chance of dying than other people of the same age in the general population (table XXXVIII, fig 14) This finding emphasises the possible importance of long-term anticoagulant therapy in reducing this risk We expressed scepticism of the value of anticoagulant therapy in the acute attack except in so far as it reduces the risk of fatal pulmonary embolism to a negligible level But to say that anticoagulants have little effect on the course of an established myocardial infarct per se is not to imply that they are valueless in preventing one Various studies suggest that long term anticoagulant therapy improves long term prognosis (Keyes et al 1953, Owren 1954, Tulloch and Wright 1954, Suzman et al 1955) But none of these have fulfilled the criteria of a fully controlled trial, and, in view of the great practical importance of the subject, it is to be hoped that such a study will be made

Summary

Among 543 patients admitted to hospital for acute myocardial infarction in 1940–54, there were 348 survivors of the acute attack, which is defined as lasting two months from admission These were all followed up until early 1956, except for 1 man who was lost after three years of follow-up

Of the survivors of the acute attack, 1 in about 7 died in the remaining ten months of the first year, and this rate was constant throughout the whole period covered by the study In the second year a further 10% died Thereafter, about 5% died each year

Bad prognostic factors, which can be recognised early in the acute attack, were evidence of cardiac failure (either left ventricular or congestive and not necessarily severe), cardiac arrhythmia including multiple extrasystoles, gross cardiac enlargement, and (though less important than the foregoing) a previous attack of myocardial infarction

Patients who displayed one or more of these features constituted a bad risk group They had four times the chance of dying in the remainder of the first year as did the patients with none of them Over the course of five years, their chance of dying was double that of the good-risk group

Age was of negligible consequence in the long-term prognosis compared with whether the patient fell into the good-risk or the bad-risk group

Among the good risk group, the main cause of death within five years of the acute attack was recurrent infarction The incidence of this was high among the patients under 60 and was the sole cause for their expectation of life being much worse than that of a sample of the same age and sex of the general population By contrast, the patients of the good-risk group over 60 years had a low rate of recurrent infarction Their expectation of life was the same as that of other people of their age and sex

Among the bad risk group, recurrent infarction was common in both main age groups In addition, cardiac failure not associated with another infarction was a potent cause of death

We are grateful to the physicians of the Radcliffe Infirmary for permission to make this study and to Dr A H T Robb Smith for permission to use the post mortem records, to Miss P Coombs, the records officer, and to Miss Betty Merry of her staff for assembling the case notes, to Miss M C McLarty for preparing the figures, and to Mrs E M Hower and Mrs B Humphreys, who in succession were responsible for the heavy clerical work

SOME POSTPRANDIAL EFFECTS OF EATING VARIOUS PHOSPHOLIPIDS AND TRIGLYCERIDES

J. R. O'BRIEN
M.A., D.M. Oxfd
HÆMATOLOGIST, PORTSMOUTH AND ISLE OF WIGHT AREA PATHOLOGICAL SERVICE

DIETS containing a high proportion of fat are thought to be related to atherosclerosis and coronary thrombosis, possibly through the hypercoagulability of the blood which sometimes follows a fatty meal.

O'Brien (1956a) has shown that single meals of 50 g. of butter, margarine, and cooking-fat all produce a similar increase in the clotting-time accelerated with Russell's viper venom ('Stypven' time). The ingestion of two eggs, which contain only 10 g. of triglyceride but 3 g. of phospholipid, produced a similar or even greater effect. The stypven time of platelet-poor plasma is very sensitive to the artificial introduction into the plasma of minute quantities of phosphatidyl-ethanolamine (P.E.), a substance that can be used instead of platelets in many clotting-tests (O'Brien 1956b). It appears, therefore, that the activity of the meal of eggs might be due, at least partly, to its content of P.E., some of which might enter the blood-stream relatively unchanged.

I report here a study and comparison of the effects of ingestion of eggs and of two kinds of phospholipid.

Bronte-Stewart et al. (1956) and other workers have shown that a diet of moderately saturated fats raises the fasting levels of serum-cholesterol and serum β lipoprotein, and that these raised levels are restored to normal if some unsaturated fats are substituted in the diet. I have tried to find out whether the difference in saturation of ingested fats influenced the changes in postprandial clotting times. Chemical analyses were made to identify the substance responsible for the observed changes in clotting-time.

Previous Work

Maclagan and Billimoria (1956) report that the ingestion of butter, but not that of margarine, shortened the postprandial stypven time. This latter observation contradicts O'Brien's (1956a) findings; but the composition of the margarine, which can vary widely, is not stated.

Keys et al. (1957) studied the effect of fatty meals on the whole-blood clotting time in siliconed tubes. The fats used were sardine oil (iodine value 185), corn oil (I.V. 120), butterfat (I.V. 38), and hydrogenated coconut oil ('Hydrol') (I.V. 2·5). These workers found that the silicone clotting time of whole blood was significantly shorter after all fatty meals, irrespective of the degree of saturation, but not after the control carbohydrate meal. Merskey (1956) and Merskey and Nossel (1957) found no change in the ordinary clotting tests four hours after large meals of unsaturated vegetable oil and of more saturated animal fats, including bacon, eggs, and butter. The only test that showed a significant shortening was the stypven time; and this shortening was observed irrespective of the type of fat eaten.

Methods

The subjects of the present experiments were eight apparently healthy men and women, aged 20–40, all of whom initially showed a well-marked and approximately similar degree of change in the coagulability of their blood after a fatty meal. One of them took part in all the experiments. For each comparison the same subjects were studied; but not all the subjects ate all the different meals.

The volunteers fasted from 8 P.M. on the preceding evening. At 9 A.M. 20 ml. of blood, called the fasting sample, was collected by venepuncture. A breakfast of toast, marmalade, tea, and a little milk was then taken with 50 g. of the prescribed fat. At $2^1/_2$ and $3^3/_4$ hours after the meal further 20-ml. samples of blood were taken.

The 20 ml. samples of blood from each venepuncture were mixed with 2·0 ml. of 3·8% sodium citrate in siliconed tubes and immediately centrifuged at 3500 r.p.m. for 20 minutes, and the plasma was separated. 1·0 ml. of this platelet-poor plasma was then diluted with 4 ml. of saline solution. To 0·1 ml. of dilute plasma in a water-bath at 37°C was added 0·1 ml. of Russell's viper venom (stypven) 1 : 100,000, and a minute later 0·1 ml. of M/40 $CaCl_2$. The time taken for clotting was recorded as the stypven time. The results shown in the accompanying tables are the averages of at least two determinations.

The rest of the postprandial plasma sample that had the shorter stypven time, subsequently called the lipæmic sample, and the fasting plasma were then taken for biochemical analyses. The total ether extractable fatty acid was estimated by a modification of the method of Van de Kamer et al. (1949), which in our hands had an error of about ± 15%. For the estimation of free and total cholesterol the method of MacIntyre and Ralston (1954) was used; this had an error of ± 5%. The lipid phosphorus was estimated in duplicate by the method described by Varley (1954); this also had an error of ± 5%.

The fats given were chosen to give as wide variation as possible.

The cod-liver oil (I.V. 165) was "non-cold filtered and deodorised" and contained 25% of the highly unsaturated arachidonic acid and 9% clupanodonic acid. The hardened cod-liver oil (I.V. 68, melting-point 36/38°C), a solid at room-temperature, was the same oil but hardened and possessed rather less than half the number of double bonds. The vegetable oil—soybean oil (I.V. 130)—contained different triglycerides, including 52% of linoleic acid, which is not present in cod-liver oil. The coconut oil (I.V. 8·5) was solid and, as well as being almost fully saturated, contained a large proportion of short-chain fatty acids, including 48% lauric acid and 17% myristic acid. These natural fats are mixtures of triglycerides but contain virtually no phospholipid. However, "pure" trilaurin and triolein containing no phospholipid were obtained in small quantities and were given as "meals."

The phospholipid that was freely available was a commercial extract from soybeans called 'Asolectin.' This contains less than 5% of triglyceride and about 30% of lecithin, 30% of P.E., and 35% of 'lipositol,' which is a mixture of inositol-containing phospholipids.

The egg lecithin was prepared specially for this experiment and contained less than 1% of P.E. Added artificially and in optimal concentration to platelet-poor plasma, it had no effect on the stypven time. 20 g. was isolated from five dozen eggs.

Results

The levels of free and of combined cholesterol in all the fasting and lipæmic plasmas from all the meals were estimated, and no significant changes were recorded.

Table I gives the results arranged in order of the iodine value of the fat eaten, and includes for comparison the average figures from previous experiments with meals containing 50 g. of butter, margarine, and cooking-fat.

TABLE I—AVERAGE % CHANGE FOLLOWING FATTY MEALS OF DIFFERENT IODINE VALUE

Fat eaten	Iodine value	Weight eaten (g.)	No. of meals	No. of volunteers	Stypven time	Total fat	Lipid phosphorus
Nil			2	2	−6	2	−1
Cod-liver oil	165	50	2	2	48	56	22
Soybean oil	130	50	6	3	39	22	8
Hardened cod-liver oil	68	50	5	3	40	27	2
Average of above fats		50	13	3	40	29	8
Average of butter, &c.*	30	50	32	8	27		
Coconut oil	8·5	50	5	3	−14	6	1
Coconut oil	8·5	100	2	2	−15	20	5

* These figures are abstracted from a previous study (O'Brien 1956a).

TABLE II—AVERAGE % CHANGE FOLLOWING FATS OF DIFFERENT CHAIN LENGTH

Fat	Chain length	Weight eaten (g)	No of meals	No of volunteers	Stypven time	Total fat	Lipid phosphorus
Trilaurin	12	10	1	1	0		
Coconut oil (48 % lauric acid)	12–20*	50	5	3	–14	6	1
Soybean oil	18*	50	6	3	39	22	8
Cod liver oil	16–20*	50	2	2	48	56	22
Triolein	18	50	1	1	23	7	3

* Chain length of major components

(O'Brien 1956a) The "average % change" for each type of estimation is obtained by taking an average of all the fasting figures and subtracting from this value the average postprandial figure This difference is expressed as a percentage of the fasting figure The chemical estimations usually showed a postprandial increase, a decrease is indicated by a negative sign The postprandial stypven times usually were the shorter When they were longer, the average per cent change is preceded by a negative sign

Table I shows that cod-liver oil produced a considerably greater postprandial increase in the total fat and in the lipid phosphorus, but only two volunteers drank this oil, and, with the considerable variation in individual responses, these changes are not significantly greater than those following the ingestion of other fats However, it will be seen that, apart from coconut oil, all the other oils of widely differing degrees of saturation gave similar results—i e, the stypven clotting-time was shortened and the total fatty acid was increased, and there was a small variable increase in lipid phosphorus

Coconut oil gave quite different results The stypven clotting time was not shortened but (on average) lengthened The increase in total fatty acid after the five meals of 50 g was significantly less than after the ingestion of the other fats Only after 100 g had been given did the fatty acids increase to a figure commensurate with those obtained after giving 50 g of the *other fats* It will be seen that, even with this larger meal the changes in clotting-time remained completely different from those after the other fats

TABLE III—AVERAGE % CHANGE FOLLOWING MEALS OF EGGS AND FATS

Fat eaten	Weight eaten (g)	No of meals	No of volunteers	Stypven time	Total fat	Lipid phosphorus
Nil		2	2	–1	–3	–3
5 eggs	25	2	2	40	38	
All fats*	50	13	3	40	29	8
3 eggs	15	4	4	29	17	17
Soybean oil	15†	4	4	12	9	0

* From table I all fats excluding coconut oil
† One volunteer ate 50 g of soybean oil

In table II the various meals are arranged in order of the chain length of the fatty acids in the triglycerides eaten It will be seen that the "meal" of trilaurin with twelve carbon atoms in the fatty acid was followed by no change in the stypven time, whereas triolein, with eighteen carbon atoms, shortened it considerably The results obtained with the mixed natural oils transcribed from table I are included It will be seen that coconut oil, with its preponderance of short-chain fatty acids, gave results similar to those obtained with pure trilaurin, whereas the other natural fats gave results similar to those obtained with triolein

In table III are reported two experiments designed to investigate the suggestion (O'Brien 1956a) that eggs are more active than might be expected from their fat content alone In the first experiment each of two volunteers ate five eggs containing 25 g of triglyceride The effects on the stypven time and plasma fat are compared with the effects in these same volunteers and one other volunteer of eating meals containing 50 g of fat (see table I) It will be seen that the changes in clotting time and the increase in total fatty acids are of the same order, although five eggs contained only half as much triglyceride, but the eggs contain about 7 5 g of phospholipid, whereas the natural fats contain almost none

In the second experiment each of four volunteers ate three eggs, containing 15 g of fat, for one meal, and 15 g of soybean oil for another meal It will be seen that 15 g of oil produced changes, in the clotting times and in the amount of total fatty acids, which are hardly significant in view of the small numbers involved The three eggs produced changes of almost double the magnitude and a considerable rise of the plasma lipid phosphorus level

TABLE IV—AVERAGE % CHANGE FOLLOWING INGESTION OF PHOSPHOLIPIDS

Lipid eaten	Weight eaten (g)	No of meals	No of volunteers	Stypven time	Total fat	Lipid phosphorus
Asolectin	20	3	3	35	12	9
	10	1	1	23	8	0
Asolectin Soybean oil	10 15	2	2	23	4	3
Asolectin	5	2	2	17		
Asolectin	2½	1	1	30		
Lecithin	10	1	1	20	27	–3
	7½	1	1	–11		
	2½	1	1	20		

Table IV summarises the results of various "meals" of phospholipids It will be seen that 20 g of asolectin considerably shortened the postprandial stypven time, slightly increased the total fatty acids (much less than did 50 g of triglyceride), and raised the level of the lipid phosphorus as much as did three eggs or 50 g of triglyceride A combination of asolectin and triglyceride did not obviously have a greater effect Small quantities of asolectin (1 0–2 5 g), that must have produced no chemical changes detectable in the blood by our methods, still produced definite changes in the clotting time The effect of various quantities of asolectin was not further investigated, because it was desired primarily to establish that the ingestion of *phospholipid* in *the* absence of triglyceride could change the clotting time

The 20 g of pure lecithin available was given in different quantities to three different volunteers It can be concluded that ingestion of this phospholipid can produce postprandial changes in the clotting time even when given in small quantities

It is obvious that the phospholipids are considerably more active weight for weight than the triglycerides

TABLE V—THE DEVELOPMENT OF "TOLERANCE" TO FATTY MEALS SHOWN BY ONE VOLUNTEER

Date	Fat eaten	Stypven time (sec)			Total fatty acid in plasma (mg per 100 ml)		
		Fasting	Lipæmic	Difference*	Fasting	Lipæmic	Difference*

Aug 10 ,,	A	56	52	4	410	446	36

* The difference in seconds or milligrammes between the fasting and the lipæmic samples
A soybean oil
B, cod liver oil
C, hardened cod liver oil

in shortening the stypven time after a meal, 10–20 g. produces about the same effect as does 50 g. of fat. A detectable change in the stypven time is produced by 2·5–5·0 of asolectin and by 15 g. of fat. It therefore seems that asolectin may be about five times as "active" on a weight basis as triglyceride. Clearly, in view of the small numbers of experiments and the variability of response, this is only a very rough approximation.

Table v shows the results in one of the volunteers. It will be seen from table i that the three fats eaten normally produced about the same changes. However, the magnitude of this volunteer's response both in the clotting-time and in the total fatty acid level, to the meals decreased significantly. During the months of these experiments his health and diet did not alter. The only unusual feature was the eating of nine meals containing 50 g. or, in one case 100 g. of fat. Only one other volunteer had as many fatty meals, and he showed little or no evidence of tolerance.

Discussion

The cause of the postprandial shortening of the stypven time remains uncertain. Poole (1955) and Robinson et al. (1955) suggested that a postprandial increase of unesterified acid might, at least partly, be responsible. They also suggest (Robinson and Poole 1956) that a postprandial rise in the level of plasma-P.E. may be responsible for the changes in clotting-time. Gordon and Cherkes (1955) have shown that there is an increase of unesterified fatty acid after a fatty meal, and a smaller but definite increase after a period of starvation. The ingestion of phospholipid, some of which may be absorbed comparatively unchanged (see below), has a considerably greater effect on the stypven time than has ingestion of a similar weight of triglyceride, and there is no evidence that the level of free fatty acid in the plasma is higher after eating phospholipids than after eating triglycerides. Thus it is possible that the stypven time under these conditions is largely measuring the level of available active phospholipid in the plasma.

With two exceptions the triglycerides, irrespective of wide variation in the degree of saturation of their fatty acids, all considerably shortened the postprandial stypven time. The exceptions were coconut oil and trilaurin, which slightly lengthened the stypven time. This suggests that the degree of saturation of the ingested fat is irrelevant to the postprandial changes observed in clotting time. The short-chain length of the fatty acids in coconut oil and trilaurin may have been responsible for their different effect. If this is so, it suggests that, in man, the short-chain fatty acids are metabolised differently from the longer-chain fatty acids.

Bloom et al. (1951) have shown that, in rats, the long-chain fatty acids down to myristic acid (C14) are transported almost exclusively in the lymph after absorption. Considerably less lauric acid (C12) and only a minor part of the absorbed decanoic acid (C10) were recovered from the lymph, and the results of other experiments (Kiyasu et al. 1952) suggest that the short-chain fatty acids are transported mainly via the portal pathway. These findings are supported by the Lund group of workers (Blomstrand 1955a and b, Borgström 1955) who showed also that the degree of saturation of the fatty acids had no influence on the way they were transported.

It is confirmed that eggs shorten the stypven time more than can be explained by their content of neutral fat; this discrepancy is almost certainly due to their high content of phospholipids, since it has also been shown that ingested phospholipid in the absence of triglycerides is about five times as active in shortening the stypven time as is the same weight of triglyceride.

Bloom et al. (1954) and Blomstrand (1955b), who produced radioactive phospholipids by biosynthesis and fed them to rats with lymph fistulæ, reported that about 20% of the activity absorbed was recovered in the lymph as phospholipid and the remaining 80% as triglyceride. After the ingestion of triglycerides only about 2% of absorbed activity was recovered in the lymph as phospholipid, in contrast to the 20% recovered after the ingestion of phospholipid. This is about a tenfold increase. If the stypven time really measures free phospholipids, these changes observed in man (weight for weight, phospholipid was about five times as active as triglyceride) are of the same order as the chemical estimations in the lymph of rats.

Egg lecithin has been shown to shorten the postprandial stypven time when eaten, yet when added artificially to starving plasma it has no effect. This discrepancy may be due to the breakdown of the lecithin during absorption and to the synthesis of other phospholipids active in this clotting-system. Blomstrand (1955b) has shown that, during the absorption of lipids, some of the molecules are broken down, and that there is randomisation during resynthesis of the phospholipids and triglycerides that appear in the lymph.

Keys et al. (1957) report that 120 g. of hydrogenated coconut oil shortens the silicone clotting-time to the same extent as do other triglycerides. This observation is hard to reconcile with the present experiments, in which the ingestion of 50 g. or of 100 g. of untreated coconut oil lengthened the stypven time. It is, however, possible that under these conditions the silicone clotting-time measures a phenomenon which does not affect the stypven time. Indeed I have found that shortening of the stypven time is not always accompanied by shortening of the clotting-time.

It has been shown that, when one man ate nine meals of 50 g. or of 100 g. of fat during three months, the postprandial changes in clotting-time decreased considerably. Swank (1954) reported that his dogs also rapidly became able to absorb large quantities of fat without appreciable alteration of their plasma-lipids. In the present study three types of response to repeated fatty meals have been noted:

(1) *An absence of effect*: one person rejected from the present series showed no change in clotting-time for five hours after eating fatty meals.

(2) *The maintenance of a well-marked change*: the volunteer who ate most meals gave as good a response at the end as at the beginning.

(3) *The development of "tolerance"* (see table v).

These three types of response are not clear-cut, and many intermediate types were seen.

The biosynthesis of plasma lipids which are presumably involved in lipid transport, can be changed by altering the type of fat in the diet, as Bronte Stewart et al. (1956) and many others have shown. It is not known whether this change or some other factor alters the response to a single fatty meal. Nor is it known if these different types of response are of any clinical significance, but clearly they might be.

The clinical importance of these results is difficult to assess. Intact platelets are inactive in the stypven test (O'Brien 1956a) and the phospholipid in them becomes available for this test only when the platelets are broken up or otherwise "activated." Presumably, therefore, the phospholipid in platelets becomes available for other in-vitro coagulation tests only after the platelets have been "activated" during the initial stages of coagulation. If lipæmic plasma contains free phospholipid, this would be immediately available for blood coagulation and would short-circuit some of the initial stages. Such blood might be more coagulable. But Merskey and Nossel (1957) found, after a fatty meal, no changes in in-vitro coagulation tests other than a shortening of the stypven time. The connection, considered more fully elsewhere (O'Brien 1957), between these highly artificial in-vitro coagulation systems and the formation of a thrombus in the coronary artery is remote indeed

Summary and Conclusions

The maximal changes in the Russell-viper-venom-accelerated clotting-time (the 'Stypven' time) of platelet-poor plasma, the total ether extractable fatty acid, the cholesterol (free and combined), and the lipid phosphorus were measured after meals containing various lipids There was no correlation between the changes in clotting-time and in the amount of total fatty acids, and only poor evidence that considerable changes in clotting time were associated with an increase in total phospholipids The cholesterol levels did not alter postprandially

Four fats of widely different degrees of saturation all shortened the postprandial stypven time by the same amount It is concluded that probably the degree of saturation of ingested fats is immaterial to the postprandial changes in clotting time Trilaurin and coconut oil either did not change or lengthened the stypven time It is concluded that fats containing short chain fatty acids may have a different effect from those with long chain fatty acids These conclusions are in agreement with other workers' results, obtained in rats and cats, which show that the degree of saturation of ingested fats does not affect the method of their transport after absorption, whereas chain length does

A "meal" of phospholipids, compared weight for weight with a meal of triglycerides, shortened the stypven time much more, suggesting that some phospholipid is absorbed relatively unchanged This result is independent of the activity or the inactivity of the phospholipid when added artificially to a test system of fasting plasma and Russell's viper venom These results may be explained by the conclusions of other workers that, during the absorption of ingested phospholipid in rats, there is extensive hydrolysis, and that randomisation occurs during the resynthesis

In one man the magnitude of the response to these fatty meals decreased during a period of three months The development of this "tolerance" is discussed

It is suggested that under these conditions the stypven time is primarily measuring the level of some phospholipids in the plasma

My thanks are due to Mrs J Cheater, A I M L T, for technical assistance and to the volunteers for their ready coöperation The lecithin was prepared in the department of medical biochemistry and pharmacology of the University of Birmingham, by Mr G B Robinson to whom I am also grateful, and I am indebted to Mr A D Wilson, of Unilever and Mr G E Tunnicliffe, of British Cod Liver Oils Ltd for the natural oils, and to Associated Concentrates Ltd for the 'Asolectin' Dr J E French very kindly helped me in the preparation of this paper

The work was made possible by a grant, for technical assistance, from the Medical Research Council

THE STATE OF DEVELOPMENT OF NEWBORN AFRICAN CHILDREN

MARCELLE GEBER
M D Paris

R F A DEAN
Ph D Camb, M R C P

VISITING WORKER AND DIRECTOR RESPECTIVELY, MEDICAL RESEARCH COUNCIL GROUP FOR RESEARCH IN INFANTILE MALNUTRITION, MULAGO HOSPITAL, KAMPALA, UGANDA

IN the course of work intended to define the psychological changes accompanying kwashiorkor it became necessary to obtain information about the psychomotor development of African children who were healthy and well nourished The development was assessed by Gesell tests, as used in Paris (Roudinesco and Guiton 1950) It was found that, up to the age of about 3 years, the development was usually in advance of European standards, and that the degree of advance was greatest in the youngest children The tests, which are normally considered to be applicable only to children more than 1 month old, were extended to younger children, and it was established that, at the age of 2 or 3 weeks, the development was equal to that of European children twice or three times that age The results were not altogether unexpected, because clinical observation of African children in the first year of life had already shown that the accepted "milestones" of development—raising the head, sitting, standing, walking, and so on—were passed at an earlier age than in European children Some of the results have already been published (Geber 1956) The present communication describes a recent extension of the work—the study of the African child at birth

Material and Method

The technique used was that of André Thomas and his collaborators (Thomas and Saint Anne Dargassies 1952, Saint Anne Dargassies 1954, Koupernik 1954) Of 107 babies, 101 were seen in the maternity department of Mulago Hospital, Kampala, where they had been born, the others had been born at home and were seen there They were all born in July or August, 1956 At birth none weighed less than 2 5 kg, and only 1 (who weighed 4 8 kg) more than 4 1 kg All the babies and their mothers were without any known disease, and delivery had not been assisted with instruments or by operation About 60 children were of the Ganda tribe, which is indigenous to the region round Kampala and belongs to the Bantu-speaking groups, and the rest were of other tribes, some of them Bantu, but others Nilotic or Hamitic No difference associated with tribe could be distinguished There was no selection of cases The nurses were asked to bring for examination any children that were available in the maternity wards Twins and children delivered either by cæsarean section or by forceps were brought with the others and were examined but were excluded from the present series For the examinations a bench or a table with a hard top was used, covered with a thick white cloth

The children numbered 107 Their ages at the time of examination were as follows less than 24 hours, 37, 25–48 hours, 45, 49–72 hours, 14, 73–96 hours, 6, 6 days, 1, 7 and 8 days, 2 of each There were 52 boys and 55 girls

Technique

Since the technique of detailed examination of newborn children is not practised widely in Britain, an account of some of the more important points may be helpful It has been drawn largely from Koupernik (1954) and Thomas et al (1955)

At birth the European child usually adopts an attitude that is a continuation of the intra uterine position the arms and legs are held tightly in flexion and the fingers clenched over the thumb; lying on his back, he has his head to one side, and the positions of his arms and legs are asymmetrical, flexion and asymmetry being characteristic of the earliest age.

The tone of the arm muscles can be judged by the resistance to extension and by pulling the hand across the thorax and over the opposite shoulder. The position is like that reached when a scarf is thrown over the shoulder, and "the scarf movement" is an appropriate name. The legs are not only flexed but also externally rotated. Their hypertonicity causes the angle at which the knees can be bent to be limited to 90°, and the angle between the legs in abduction to be only 60° (a child whose legs are continuously in extension, or whose hands are permanently open, is deemed to be pathologically hypotonic). If the child is placed on his belly he turns his head to the side, with his cheek laid flat. The head cannot be turned from this position, nor, if the chin is put to the table, can the head be raised to free it. The rest of the body is bunched up, with the arms bent and the elbows in to the sides and the thighs flexed so that the buttocks are raised. Sometimes, in this position, the child makes a kind of creeping movement (reptation). If the child is put into the sitting position, his trunk tends to collapse, with a kyphosis extending from the neck to the sacrum. The head falls forwards, and falls back if the trunk is made to lean backwards. The falling back, or rather the "head lag" is seen best when the child is drawn up by his hands into a sitting position.

Many details of reflex activity have been described. The most spectacular and one of the most consistent in European children, is the Moro reflex. It is best seen when the child is on his back and can be elicited in many ways, including knocking sharply on the table on which the child is lying, and by almost any sudden movement of the limbs or trunk —for instance, by raising the body by pulling on the arms until the head is just clear of the table and letting go. The arms are thrown out in full extension (one name for the reflex is "the arms of the cross"), the back is extended or arched, the head is drawn back, the fingers are fanned out, and the legs are extended. After the extension there is a characteristic return of the arms across the trunk.

The grasping reflex is well known and is also very constant. It should be equal in left and right hands and has two components, one the closing of the hand when the palm is pressed, and the other the maintenance of tension in the flexors, which makes it possible to raise the whole child by a stick grasped in the two hands.

Two other important reflexes can be shown when the child is held standing with his feet on the table: one, which can be called the "straightening reflex," is a tendency of the whole body to be straightened from its usual flexion; the other is the "automatic march" which is a walking step made with the knee flexed and the toes raised, the heel being the first part of the foot to touch the ground.

Tendon-reflexes are usually easy to find but vary with the tone of the part of the body.

Of the cutaneous reflexes the easiest to examine is the plantar reflex. It can be elicited over a large area of the outer side of the legs, as far up as the thighs, but is complicated by the grasping reflex of the toes, which is much like that of the fingers.

Among many other reflexes may be mentioned the ciliary and the photomotor (the tight closing of the eyes when the eyelashes are stroked or a light is shone into them), the "doll's eye" (the movement of the eyes in the opposite direction to passive movement of the head), the auricular (the turning of the head away when the lobe of the ear is rubbed), and the masseteric (the raising of the jaw when the chin is tapped).

Most of the hypertonicity disappears in the normal European child after 6–8 weeks, and the general attitude of flexion is lost. The ability to control the head so that it no longer flops forwards or back, and to straighten the back in the sitting position is not acquired until 8–12 weeks. The Moro reflex, the automatic march, and the straightening reflex do not persist after 6–8 weeks.

Children at about 2 weeks follow with their eyes near moving objects and at 3 or 4 weeks start to move the head to help the pursuit.

Results

It was immediately obvious that the distribution of muscle tone in the African child differed from that in the European. When the African child was lying quietly at rest, his flexion was much less accentuated (fig. 1). Often the knees were only slightly flexed, and only one of the arms was flexed, with its hand half-open; the other arm might be fully extended, with its hand open completely.

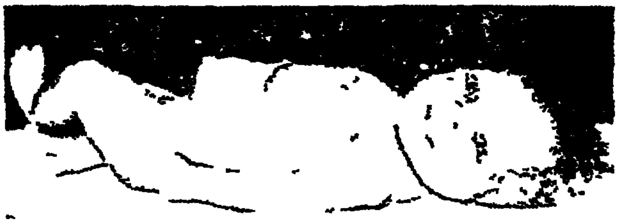

Fig 1—Aged 48 hours lying with limbs extended: cheek is slightly raised, and liveliness of eyes is remarkable.

When the child was put down on his back his head was usually on one side but could be turned from side to side and held in the median position. The eyes were wide open, and had a lively look. In many children, even in the first days moving objects could be followed with the eyes, and rotation of the head accompanied the pursuit. There was plenty of spontaneous activity, and it was not unusual for the child to turn half on his side. The activity of the arms and legs was bilateral and symmetrical but greater in the legs than in the arms. The legs were chiefly flexed and extended but were also crossed and uncrossed. The feet were usually rotated so that the soles faced each other. The arm movements were not so brisk as those of the legs. The flexion of one arm and extension of the other have already been mentioned; when the child had his head to one side, the arm of that side would often be abducted and lying beside the face. The hands, which were usually open, were moved in all directions and were carried frequently to the face, particularly to the mouth. One child, a day old, who had received at birth a slight scalp wound in the occipital region, continually fingered the bandage over the wound. The thumb was less active than the other fingers but was often in extension. The fingers were spread from time to time.

When he was placed on his belly the child immediately turned his head to one side or (even more remarkable) raised his head, propping himself on his forearms (fig. 2). Sometimes the head was only raised momentarily in the median position and was then lowered, resting on the chin, but most of the children raised the head for several seconds, with the lumbar lordosis and the flexion of the legs increased, and with the arms pressed firmly on the table, the elbows against the body, and the forearms straight ahead. The hands were open, and sometimes the fingers clawed and scratched. The knees were as often flexed as partly extended, but the thighs were almost always flexed on the abdomen so that their fronts were rarely in contact with the table. The legs were less active than when the child was on his back but fairly often they made creeping movements.

By far the most remarkable feature of the prone position was the control of the head and neck; it seemed almost as though all efforts were concentrated on that

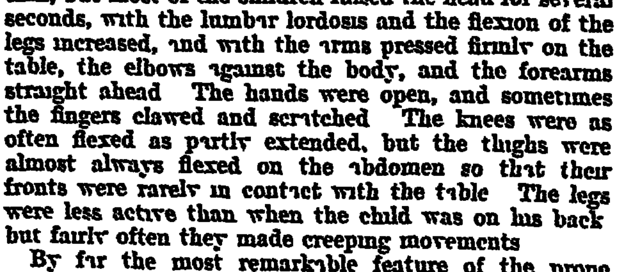

Fig 2—Same child as in fig 1, raising chin clear of table.

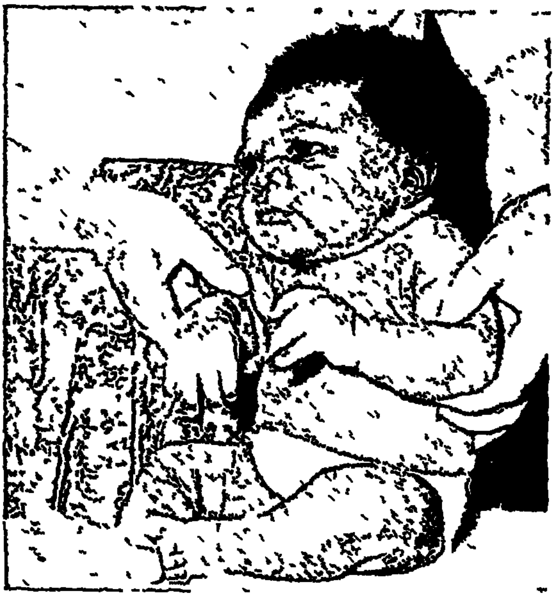

Fig 3—Aged 9 hours, able to prevent head from falling forwards

control, which was evident again when the children, lying on their backs, were drawn *up into a sitting position* (figs 3 and 4) Of the 107 children, 90 could prevent their heads from falling back In these children the trunk remained straight

When the child was sitting the head remained in the median position and was sometimes turned from side to side before finally falling forwards When it had fallen, many children could immediately raise it again The back was straight and upright, or inclined forwards, and a kyphosis was exceptional The knees were moderately flexed, and the feet were rotated internally

Some children, when being drawn into a sitting position, pressed on their heels as they were raised and straightened themselves until they were nearly standing Held upright with the feet touching the table most of the children produced a straightening reflex, some pressing hard with both feet, and some with only one A few children merely bent the legs The "automatic march" reflex was found in only a few children, all aged 1–3 days

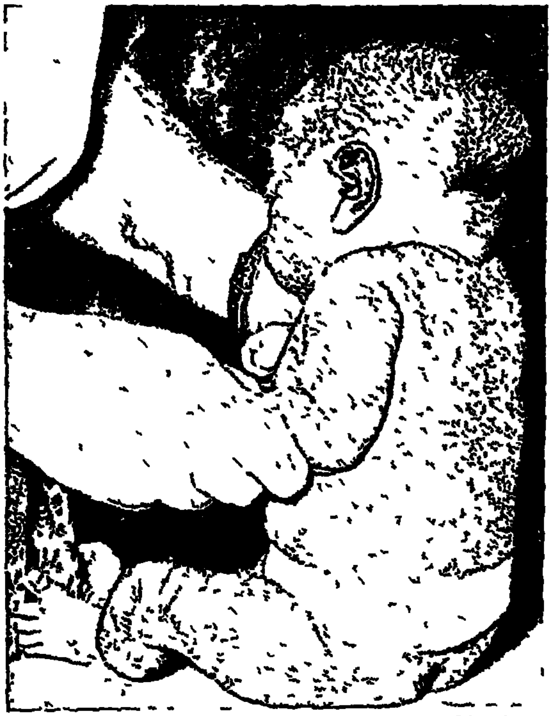

Fig 4—Aged 28 hours, held sitting, back is straight and head upright

The Moro reflex was by no means constant In some children, mostly aged 1 or 2 days, the reflex was brisk and full, with extension and abduction of the arms and the usual slow return to the position held before, but in others, whatever means were used for trying to elicit the reflex, the amplitude of the response was poor The reflex was found in no child aged more than 4 days (*Although* the present communication is limited to the description of children who weighed 2·5 kg or more, it is relevant that some smaller children, who might have been premature, produced a thoroughgoing reflex) The grasping reflex was also inconstant, and if the child closed his hand on the object pressed into his palm he rarely continued to hold it firmly but soon relaxed his fingers and allowed the hand to resume its former attitude

Further examination of tone showed that the extensibility of the flexors, in arms as well as legs, was much greater in African children than in European The flexion was less hypertonic, it was easy to extend the forearms, and they did not return immediately into flexion but usually remained outstretched On the contrary, the angle of flexion of the wrist was greater than 90° (fig 5) The scarf movement, the test of adduction of the arm, could be made easily Abduction and the carrying of the forearm behind the shoulder also met with little resistance Similarly, in the legs the popliteal angle was more than 90° and the angle between the straightened abducted legs more than 60°

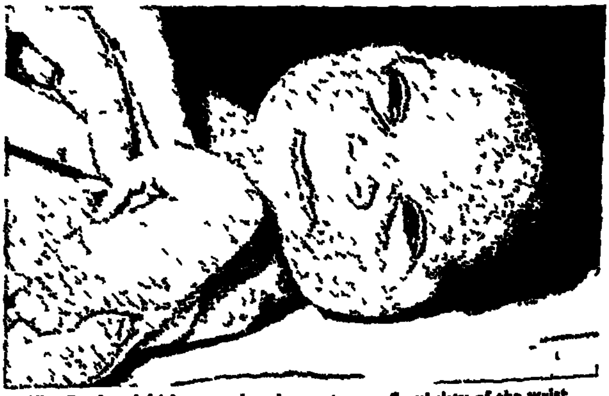

Fig 5—Aged 14 hours showing extreme flexibility of the wrist

On the whole, then, the tone of the flexors in the African children was less in the limbs but more in the head and neck Other reflex activity—ciliary, photomotor, masseteric, the sucking reflex, and the turning of the head on stimulation of the corners of the mouth—was present On the other hand, the "doll's eye" and auricular reflexes could not be elicited Of the tendon reflexes the patellar was very easy to elicit and the radials were almost as easy Curiously, despite the relatively light tone of the arm flexors, the olecranon reflex could not be obtained The cutaneous plantar reflex was nearly always extensor, and the grasping reflex of the toes was more constant than that of the fingers

When the child was held horizontally face downwards on the open hand of the examiner, the back was straight, the head was kept from falling forwards, and the legs were usually extended in the line of the trunk (fig 6) Held similarly, but face upwards, the child let the head fall back, and his back arched

So far as could be determined in this series the results did not vary with the sex of the child, its birth-weight, or the parity of the mother Unfortunately it was impossible to discover the length of the period of gestation, because the dates of the last menstruation were not accurately known

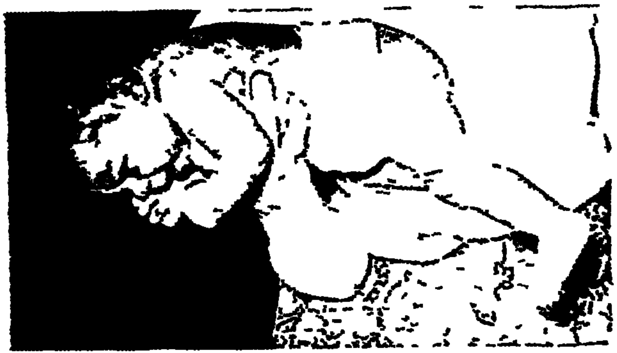

Fig 6—Aged 43 hours: back is straight, head controlled, and left leg extended

Discussion

There seemed to be no doubt that these African children had been born at a more advanced stage of development, judged by the method used, than the normal European child The results of the examination were so consistent, and the degree of advance was so great that there was little room for uncertainty Much of the activity corresponded to an age of 4–6 weeks Some was even more precocious for example, the raising of the chin and the scratching of the fingers on the table, when the children were placed on their bellies might be expected at 6–8 weeks, and so might the maintenance of the head in the mid-position when they were on their backs

We do not intend at this stage, to advance theories or facts in attempted explanation, but it is clear to us that the state at birth is consistent with some clinical observations that the African child sucks vigorously at the breast almost from the first hour, and that he passes the milestones of development at a very early age It is consistent also with the findings of psychomotor precocity in the earliest years to which we have already alluded As we have said elsewhere (Geber 1956) an extensive investigation of all facets of the development of the African child is imperative A more detailed study of the newborn child is planned, and will include twins, children born by cæsarean section, others whose birth has been associated with trauma, and others born before term The last named should be especially interesting, it is well recognised that African children whose weight at birth would by ordinary standards cause them to be classed as "premature," are often sturdy and active and can be reared without the special care that has to be lavished on European children of the same weight

It is conceivable even if it is in our opinion unlikely, that some of our findings could be explained by the existence of local conditions obtaining at Kampala, which is almost on the equator, and about 3500 ft above sea-level We are prepared to consider a number of possibilities but we have one piece of evidence that may be helpful in making a judgment At the same time as the African children a group of 15 European children—all that were available in the European Hospital, Kampala—and another group of 60 Indian children in the Asian Hospital were studied by the same method The European children gave exactly the results that have been found in Europe and the Indian children gave almost similar results Neither group showed any great degree of overlap with the African children The work on the European and Indian children will be reported when it has been extended to greater numbers at the moment it may perhaps be admitted as a confirmation, in part of the validity of the findings in the Africans

Summary

The technique of neurological examination evolved by Andre Thomas in European children is described

107 newborn African children who were considered to be normal at birth were examined by this method

They proved to be at a more advanced state of development than newborn European children

The advance was shown chiefly by a lesser degree of flexion, by a remarkable control of the head, and by the frequent absence of primitive reflex activity.

The results were consistent with clinical observations and Gesell tests made on young African children

We are very grateful to Prof Coralie Rendle-Short, the head of the obstetrical and gynæcological departments at Mulago African Hospital and the European and Asian Hospitals, Kampala, for allowing us to visit the maternity wards and to examine the children there, and to the nurses, who accepted most willingly our disruption of their routine We have also to thank Dr Saint-Anne Dargassies for her assistance in the use of technique of examination, and Dr. Andre Thomas for his criticism of our findings The expenses of the investigation were paid from grants made by the International Children's Centre, Paris, and the mental health section of the World Health Organisation. and we thank especially Dr Maurice Gaud, in charge of the African affairs of the Centre, and Dr Ronald Hargreaves, formerly chief of the section.

LONDON HOSPITAL

PATIENTS with carcinoma of the stomach are more likely to belong to blood-group A and those with duodenal ulcers to group O than are controls; and patients with gastric ulcers come somewhere in between (Aird et al 1953, 1954, Clarke et al. 1955, Koster et al 1955) Koster et al suggested as an explanation that blood-group A was associated with a tendency for the mucosa of the body of the stomach to atrophy, and that the atrophic mucosa and consequent hypochlorhydria produced a lessened liability to duodenal ulcers and an increased liability to carcinoma

Scepticism about the association between hypochlorhydria and the origin of gastric carcinoma led us to test this hypothesis by seeing whether blood group A was in fact associated with carcinoma of the body rather than with carcinoma of the antrum We could do this because in a series of cases of relatively early carcinoma we had already determined the probable site of origin

Contrary to what the hypothesis demanded, there was an excess of group O in the carcinomas of the body, and of group A in carcinomas of the antrum (Jennings et al 1956) These results being only on the borderline of statistical significance they were not reported until further study showed that simple gastric ulcers behaved in a similar way—i e , simple ulcers of the antrum tended to be associated with blood group A, whereas the common gastric ulcer just above the angulus was associated with blood-group O.

Publication of our results was deferred because of criticism of our previous paper by Haddock and McConnell (1956), which led us to restudy our original material together with additional cases seen in 1954–56 Meanwhile Billington (1956a and b) published results which agree closely with ours It seems possible or probable that the results of Haddock and McConnell differ owing to the difficulty of deciding the site of origin of a gastric carcinoma unless the decision is made at operation by comparing the clinical history and X ray films with the fresh specimen In the fixed specimen uninvolved parts of the stomach shrink more than the growth, and consequently lesions of the body often seem to arise only a short distance in front of the pylorus In other cases, where there has been delay in making a diagnosis, a prepyloric carcinoma may extend upwards to involve much of the body of the stomach

Material and Methods

Up to July, 1956, 216 partial gastrectomies for gastric ulcer (uncomplicated by a duodenal ulcer or a scar) were indexed in the combined medical and surgical peptic-ulcer clinic, most of them since 1950 The decision whether an ulcer near the sphincter was prepyloric or duodenal was made at the time of operation by the surgeon , or, if he was doubtful, the pathological department was asked to report on the nature of the mucosa above and below the lesion All ulcers across the sphincter —i e , with gastric mucosa above and duodenal below—were classified as duodenal

In 5 of the 216 cases there is no record that the blood group was determined , 6 patients belonged to groups B and AB , and 13 other cases are omitted because the operation was an emergency one, there had been no previous barium meal, and the site of the ulcer relative to the angulus was uncertain

The remaining 192 cases were classified into three groups by inspection of X-ray films taken in the erect position The difficulty of deciding whether an apparent prepyloric ulcer was really a sphincteric or a duodenal one did not arise, because the method of selection ensured that all the ulcers were gastric Ulcers associated with a “ hanging bag ” deformity—i e , ulcers starting at the angulus but eventually drawn towards the pylorus by scarring and contracture of the prepyloric lesser curve—were classified as antral Other ulcers at the angulus or on the vertical part of the lesser curve were classified as “ mid gastric ulcers ” The third group of “ high ” gastric ulcer consisted of those on the sloping part of the lesser curve below the cardia No attempt was made to estimate the distance from the cardia in centimetres

Results and Discussion

In the accompanying table the gastric ulcer patients are compared with our previously published carcinoma series At each site in the stomach the relative proportion of blood groups A and O is similar in simple ulcer and carcinoma, group A being more frequent in antral lesions (A/A + O = 0 7), and group O in lesions of the body (A/A + O = 0 45) In both sexes group A predominates in antral lesions, but the excess of group O in lesions of the body is only found in males This difference between the sexes in lesions of the body is unexplained and needs confirmation The few high gastric ulcers and carcinomas of the cardia resemble the antral lesions in showing an excess of group A These results are similar to those reported by Billington (1956a and b), who did not, however, distinguish between the sexes

Hitherto it has been thought that gastric carcinoma was associated with group A and peptic ulcer with group O Our results support Billington's (1956a) suggestion that the important association is between the *site* of the lesion and the blood group, and that the *nature* of the lesion, whether simple ulcer or carcinoma, is irrelevant The overall association of carcinoma of the stomach with group A, and of gastric ulcer with group O, results from the fact that most carcinomas occur in the antrum (in lesions of which group A predominates) and most ulcers in the body (in lesions of which group O predominates) The effect of comparing all carcinomas with all ulcers has been to confound a real association between blood-group and the part of the stomach affected, and to produce a spurious association between blood group and the type of lesion, whether carcinoma or ulcer

192 GASTRIC ULCERS AND 119 CARCINOMAS OF THE STOMACH CLASSIFIED BY SITE, SEX, AND BLOOD GROUP

Lesion	Males					Females		
	A		O		Ratio A/A+O	A	O	Ratio A/A+O
Prepyloric ulcer	25	55(43 3)	17	32(43 6)	0 60	4	3	*
Carcinoma of pylorus and antrum	30		15		0 67	12	5	0 70

All carcinoma	47		39		0 55	23	10	0 70
	117		118			49	27	

* Insufficient for calculation

†Expected figures (in parentheses) based on the hypothesis that there is no relation between site and blood group

χ^2 for men alone = 13 3 (2 degrees of freedom) p< 0 0025

χ^2 for both sexes = 7 5 („ „ „ „) p< 0 025

Summary

In 192 patients with gastric ulcer, and 119 patients with carcinoma of the stomach, blood group A predominated when the lesion was in the pyloric antrum and blood group O when it was in the body of the stomach

The association between gastric carcinoma and blood group A on the one hand, and that between gastric ulcer and blood group O on the other, may be attributable to the fact that most carcinomas are in the antrum, whereas most gastric ulcers are in the body of the stomach

We wish to thank Dr H B May, director of the clinical laboratories, for providing the results of the blood group determinations

“ Because the problem of nutrition is largely a cultural one, the approach to its solution must be principally through cultural means But what is the problem of nutrition which we are concerned to solve ? It is, surely, how one can get human beings to eat foods which at every stage of their growth and development are those most likely to contribute to their optimum health No matter how complete our knowledge of the biochemistry, the physiology, and the nutritional value of food may be, unless we attend to the sociopsychologic or cultural factors first we are not likely to succeed in our endeavors ”—M F ASHLEY MONTAGU, PH D , *Amer J clin Nutr* 1957, 5, 237

MYASTHENIC CRISIS

THERAPEUTIC USE OF *d*-TUBOCURARINE

H. C. CHURCHILL-DAVIDSON

From St. Thomas's Hospital

IN the past few years progress has been made in determining the mechanism of the neuromuscular failure in myasthenia gravis. The former concept that a "circulating curare-like substance" was responsible for the neuromuscular block has now been virtually abandoned in favour of an alteration in the response of the motor end-plate to acetylcholine or one of its breakdown products (Churchill-Davidson and Richardson 1953). Recently the work of Grob et al. (1955) has indicated that an abnormal response of the motor end-plate to choline (a derivative of acetylcholine) may be the primary factor.

Since 1934, when Mary Walker introduced the use of physostigmine for the purpose, the treatment of myasthenia has centred on various anticholinesterase drugs. Some patients respond more readily than others, and Rowland et al. (1955) have shown that occasionally these drugs, instead of improving the patient's muscle weakness, bring about a rapid deterioration. We describe here a case of this kind and report a new therapy for such patients which is consistent with the present concept of myasthenia.

Case-report

Our patient was a housewife, aged 56, weight 12 st. 3 lb. She was admitted to hospital for investigation.

APRIL, 1954

She had had a drooping right eyelid for three months, slurring speech for two months, and weakness of the jaw for six weeks. These signs were all made worse when she became excited and at the end of the day. The jaw weakness was such that she had to hold her chin up when talking or eating. She could take only semi-solid foods.

Investigations.—No radiological evidence of a mediastinal mass. Serum-creatinine level 0·98 mg. per 100 ml.; serum-creatine 0·35 mg.; serum-cholesterol 118 mg. Hb 84%. Intramuscular neostigmine 2·5 mg. produced dramatic improvement in the muscle weakness. Intravenous decamethonium 2·5 mg. produced peripheral and facial muscle weakness with severe dysphagia and dysphonia. The action potential of the hypothenar muscles (after supramaximal stimulation of the ulnar nerve at the wrist 10 times a second) showed a 10% reduction of the control value. Subsequently, intravenous 'Tensilon' 10 mg. led to a dramatic improvement in the muscle weakness for about two to four minutes.

The reactions are typical of generalised myasthenia gravis in the second or "dual" phase (Churchill-Davidson 1950).

Treatment with pyridostigmine ('Mestinon') 60 mg. four times a day produced good results. After consultation, thymectomy was considered advisable.

MAY, 1954, TO NOVEMBER, 1955

Thymectomy.—The thymus gland was removed in May, 1955, by Mr. N. R. Barrett. It weighed 33·5 g. Microscopy showed "evidence of hyperplasia and atrophy in the mass, but the predominant change was hyperplasia of the large thymus cells. The process appeared to be analogous to nodular hyperplasia in other organs affected by hormones—for example, chronic mastitis. There was no evidence of neoplasm."

Progress.—The patient made an uneventful recovery. Three weeks later she left hospital considerably improved but taking twice the amount of pyridostigmine that she took before the operation—i.e., 60 mg. two-hourly. She was seen regularly at the follow-up clinic every two months, but during the next fourteen months her condition gradually began to deteriorate despite temporary improvement obtained by increasing the dose of pyridostigmine.

DECEMBER, 1955, TO MARCH, 1956

Readmitted in December, under the care of Dr. H. J. Anderson, she felt "terribly tired" and had a myasthenic facies with considerable drooping of both eyelids.

Treatment.—Neostigmine, 22·5 mg. two-hourly for seven doses daily, led to a temporary improvement lasting three days, but she had to be roused regularly during the night; otherwise she was too weak even to swallow in the morning. Pyridostigmine 120 mg. was again tried as the last dose at night in the hope of getting a more prolonged response, but there was only slight improvement. Then neostigmine 30 mg. two-hourly for eight doses daily was tried, again with temporary improvement.

As increasing doses of neostigmine were not producing any general improvement in muscle strength, and the patient was too ill to undergo thoracotomy, she was given another anticholinesterase drug—WIN 8077 (Schwab et al. 1955)—two-hourly in a dosage which gradually increased from 10 mg. initially to 30 mg. two-hourly on the third day. Muscle strength greatly improved on this dosage but was maintained for only about an hour of the two-hour interval between doses; hence, by the time the next dose was due the patient had again become very weak.

Cholinergic Crisis.—On the fourth day after the start of treatment with WIN 8077 the patient suddenly collapsed while on a bedpan. Respirations ceased, and the pulse became feeble. Artificial respiration was begun, and the house-surgeon gave intramuscular neostigmine 2·5 mg. This dose was repeated thirty minutes later, when there was still no sign of spontaneous respiration. The patient was then intubated and maintained on manually controlled respiration with a nitrous-oxide/oxygen mixture. Intravenous tensilon 10 mg. produced no response, and it was then concluded that the patient was probably having a "cholinergic crisis"—i.e., an overdose of anticholinesterase drugs (mainly WIN 8077).

Weak respiratory activity returned three hours later, but could be temporarily abolished by intravenous tensilon 10 mg.

No further drugs were given that day. Five hours later the patient breathed spontaneously and appeared to improve after the intravenous injection of tensilon 10 mg.; so neostigmine 2·5 mg. was given intramuscularly. During the next twenty-four hours the patient twice stopped breathing, on each occasion soon after taking neostigmine 22·5 mg. by mouth.

At this point it was decided to withhold anti-cholinesterase drugs for some days and to maintain adequate artificial ventilation.

Tracheotomy was performed under thiopentone/nitrous-oxide/oxygen anæsthesia, and a cuffed tube was inserted. Ventilation was then maintained with air (supplemented by two litres of oxygen per minute) on a Beaver mark II respirator. Adequate nourishment and fluids were given through a stomach-tube. Sedation was achieved with amylobarbitone sodium and chlorpromazine.

At the end of ten days on this routine the patient was again given neostigmine 22·5 mg. two-hourly. The response was dramatic. Next day all signs of the ptosis had gone, and she could swallow and talk. She dispensed with the respirator during the day but was not sufficiently confident to do so at night.

Progress.—A week later her morale was high, and the improvement in the myasthenic symptoms was striking; but thrombosis of both deep femoral veins necessitated anticoagulant therapy. Four weeks later she was able to get out of bed, and for the first time for many months, could see clearly to read the papers; she was able to knit, and write. The tracheotomy tube was withdrawn, and the wound allowed to close.

Seven weeks later she was discharged convalescent, taking neostigmine 22·5 mg. two-hourly for eight doses daily.

MARCH TO JULY, 1956

Nine weeks later her myasthenic symptoms started to return; she became very tired, and her left eyelid was drooping again.

She was readmitted to hospital, and gradually over the next few weeks her weakness increased, swallowing became extremely difficult, and her voice was hardly audible. She had to be roused at night to receive tablets because she was otherwise too weak in the early morning. Pyridostigmine was again tried as a substitute for neostigmine as the last dose at night, but again this only led to some temporary improvement

Her general condition became so poor owing to continuous salivation and inability to swallow sputum, poor respiratory excursion, and grossly inadequate diet, that it was decided to reinsert the tracheotomy tube and to maintain nourishment through a nasal stomach tube

Second Tracheotomy—Thiopentone 0 15 g and succinylcholine 40 mg were given, and respiratory activity was paralysed for four and a half minutes, during and after which respiration was controlled with a nitrous oxide oxygen mixture through an endotracheal tube up to the time that the tracheotomy tube was inserted

Progress—All neostigmine therapy was stopped On recovering consciousness half an hour later the patient breathed unaided, but four hours later she became cyanosed and very distressed, with poor chest movements The Beaver respirator was again used Her jaw became so weak that it had to be permanently supported by a bandage For the next fourteen days respiration was controlled automatically and adequate nourishment was given through a nasal stomach-tube Light suction of the trachea and bronchi was performed half hourly, or whenever necessary

After a fortnight's treatment the patient was again put back on neostigmine 22 5 mg two hourly for seven doses followed by pyridostigmine 120 mg two hours later The effect was again impressive Gradually over the next few days she could do more and more until she was strong enough to get out of bed for a short time, swallow liquids, knit, write, and read the paper The improvement was maintained for about two weeks and then gradually began to wear off until she again became pitifully weak, being unable to swallow liquids or to breathe adequately without assistance

The pattern of events became remarkably cyclic a period of improvement in muscle power with neostigmine was followed by a gradual deterioration, and then, after a complete rest from drug therapy, a return of the response to neostigmine It was assumed that the dose of neostigmine used after the initial improvement was repeatedly poisoning her, and it was decided to give her another fourteen days of complete rest from all drug therapy but then to try much smaller doses of neostigmine

At the end of the fortnight's complete rest, using the Beaver respirator, the patient was given neostigmine 22 5 mg t d s Again there was an initial improvement in muscle power, enabling her to close her jaw and swallow liquids, but it lasted only for short periods after swallowing the neostigmine After a fortnight the initial improvement began to subside The morale of both patient and attendants was beginning to fall, and desperate measures were now considered necessary

Thyroid Treatment—The first was to try to make her thyrotoxic to see if the myasthenic symptoms would improve After eight days on thyroid extract gr 10 t d s her personality had greatly changed she was irritable, weepy, and unable to be pleased Three days later she became completely unmanageable, so the thyroid treatment was abandoned During this period there was no sign of any improvement in the myasthenic state

At this point the patient's morale was very low, and she could only talk feebly while supporting her jaw with her hand Her diet was entirely fluid because she could not chew or swallow solids, and she seemed completely unable to move her tongue She could neither knit, write, nor read Repeated doses of chlorpromazine 50 mg p o and morphine gr $^{1}/_{8}$ were given with heavy barbiturate sedation at night

AUGUST TO OCTOBER, 1956

(Curare Therapy)

Repeated attempts to "rest" the motor end plate by withholding neostigmine had led to temporary but clear improvement on three separate occasions It was decided, therefore, to go one stage further and to attempt complete "rest" of the motor end-plates for a week by screening them from activity by using repeated doses of *d* tubocurarine

On Aug 27 thiopentone 0 3 g was given, followed by *d* tubocurarine 15 mg Amylobarbitone sodium gr $3^{3}/_{4}$ and chlorpromazine 50 mg were given eight hourly as general sedation. Respiration was maintained on Beaver respirator (mark II) with an expiratory volume of 450–550 c cm per breath at a rate of 12 per min Muscle paralysis was measured both by the visible signs of movement and by stimulation of the ulnar nerve at the wrist at a twitch rate (i e, 10 per sec) and observing the absence of a visible response in the hypothenar muscles Any sign of returning muscle activity was taken as an indication for a further dose of curare The degree of consciousness was measured daily with an electroencephalograph and the appearance of alpha rhythm was taken as a guide for increased sedation In the early stages more frequent electroencephalographic measurements are advisable Electrolyte balance, prothrombin time, urine output, pH, and plasma-bicarbonate level were measured daily

The intake of fluids averaged 3240 ml in twenty four hours A diet of 1500 calories contained per each 12 oz

Protein	105 0 g	Vitamin B_1	3 9 mg
Fat	55 0 g	Riboflavine	3 7 mg
Carbohydrate	150 0 g	Nicotinic acid	25 0 mg
Calcium	2 8 g	Pantothenic acid	10 0 mg
Phosphorus	2 7 g	Choline	250 0 mg
Sodium	1 8 g	Pyridoxine	1 4 mg
Chloride	2 5 g	Vitamin B_{12}	7 0 µg
Potassium	3 7 g	Vitamin C	34 0 mg
Iron	37 0 mg	Vitamin D	750 0 units
Vitamin A	3750 0 units	Vitamin E (acetate)	18 0 mg
		Vitamin K	3 7 mg

The dosage of curare was as follows

1st day (7 0 P M –midnight)	65 mg	6th day	90 mg
2nd day	155 mg	7th day	115 mg
3rd day	140 mg	8th day	60 mg
4th day	140 mg	9th day	Nil—respirator continued
5th day	110 mg		
Total dose of curare			875 mg in eight days

8th day The last dose of *d* tubocurarine was given at 11 20 A M By 5 0 P M right thumb and wrist were seen moving By 7 0 P M lower lip and both eyelids were showing weak but vigorous movement Able to answer questions by squeezing hands Attempts being made to speak

9th day after quiet night now sitting up with eyes wide open Jaw muscles regaining good tone and able to eat light breakfast Off respirator for a few hours at a time Still no neostigmine given

10th day remarkable improvement Able to eat full breakfast, and steak for lunch for first time since admission to hospital Able to get out of bed unaided but still unsteady on legs Now off respirator altogether

11th–20th days continuous, steady, daily improvement Without any neostigmine patient now eating better than at any time for two years Jaw muscles feel firm and eyes are widely open Knitting, reading, and writing well Able to walk length of ward slowly but unaided

21st day left eyelid notice drooping towards end of day

22nd–25th days steady return of myasthenic symptoms, including drooping of eyelids, husky voice, dysphagia, jaw weakness, and general tiredness

Neostigmine therapy on a reduced scale was started again in the dosage of 22 5 mg t d s effect was again dramatic all signs of the myasthenia vanished and the patient could once more eat, see clearly, talk, and walk During the next week the patient was gradually restored to full confidence As there were slight myasthenic signs in the late evening, the dose of neostigmine was increased to four times a day

Four weeks after the end of the curare treatment the patient left for a weekend in the country after having been nearly a year in hospital After a further week's observation in hospital, during which time her tracheotomy tube was removed, she was finally discharged to her home on Oct 12

Condition on Discharge—She was still on the same dosage of neostigmine, both eyes were widely open at all times and she was eating well, reading, knitting, and talking strongly There was no apparent weakness of the facial muscles and she smiled freely Despite her weight of nearly 13 st she walked well and climbed stairs unaided

Final Illness—Unfortunately her only relatives lived in a remote part of Scotland, but in view of what she had already endured, and fully realising the possible consequences, we allowed her to return home We followed her condition by constant correspondence, from which it appears that her improvement was maintained for a further six weeks, making a total of about three months After this, first the left eyelid started to droop, and then the jaw muscles became weak again, despite a constant dosage of neostigmine The general weakness became worse The patient died quite unexpectedly during the night some three weeks later, from what appeared to be an acute onset of respiratory failure

DISCUSSION

The main trouble in myasthenia gravis appears to be an alteration in response of the motor end-plates to acetylcholine or one of its breakdown products (Churchill-

Davidson and Richardson 1953) This supposition is supported by the finding of Grob et al (1955) that choline (a breakdown product of acetylcholine) produces a non depolarisation block in myasthenic patients—i e, instead of producing a simple depolarisation of the muscle fibre as in the normal subject it may produce a prolonged neuromuscular block similar to that produced by *d*-tubocurarine There is no evidence that the choline of myasthenic patients differs in any way from that in normal subjects, on the contrary, experience with decamethonium suggests that this explanation is very unlikely, because it is not the drug that has changed but the response of the motor end-plate

The action of neostigmine at the motor end-plate has not been fully established There is no doubt that its major action is to depress the activity of both the plasma and the true cholinesterase, with the result that the concentration of acetylcholine at the motor end-plate increases Apart from this, it has an action similar to that of acetylcholine on the motor end-plate and possibly on the muscle fibre

The therapeutic value of neostigmine in myasthenia is generally attributed largely to its anti cholinesterase properties, but this may not be the sole reason for it Rowland et al (1955) have shown that, whereas one patient tolerated as much as 2500 mg a day by mouth, another became extremely weak after receiving 16 mg intravenously in ninety minutes This variability in response to neostigmine, not only in different patients but also in the same patient at different times, is characteristic of the disease The altered response of the motor end-plates might be explained by an alteration in the ratio of acetylcholine molecules to those of choline, the former producing depolarisation during their fleeting life-span, and the latter persisting indefinitely and producing a non-depolarisation block like that of *d* tubocurarine

This may help to explain why myasthenic muscle which ceases to respond to neostigmine can be made to respond again if the neostigmine is withheld for a while The present case illustrates this point well, for the anti-cholinesterase drugs apparently induced a "cholinergic crisis" or respiratory failure Then, after a suitable rest, neostigmine produced a striking response in muscle-power, but gradually over the next few weeks this response deteriorated Again, on two separate occasions a rest produced a dramatic improvement, only to be lost a few weeks later It seems almost certain that it was the neostigmine itself that was gradually producing this deterioration The gap between the improvement in muscle strength and the period of deterioration due to possible poisoning became narrower and narrower as the therapy continued, only to widen again after a suitable rest, yet a small concentration of neostigmine was essential to normal respiration and fundamental activity

The fact that the periods of rest were always followed by improvement in the response to anti-cholinesterase therapy led to the next logical step—an even more efficient method of resting the motor end plates Conscious patients, even when on a breathing machine, use their muscles to a limited extent We assumed that if such a patient were sedated and completely paralysed, then only a small amount of acetylcholine would be produced at the nerve terminal The presence of a high concentration of a muscle relaxant—e g *d* tubocurarine—would so raise the excitation threshold of the motor end plate that the concentration of acetylcholine ions would be insufficient to cause stimulation Thus the motor end-plate would enjoy a period of complete rest In such circumstances any substance, whether anti cholinesterase or choline, that has accumulated at the motor end plate would be removed This rather slender hypothesis was the basis for trying what might otherwise be described as *dangerous* treatment—namely, to give large doses of *d*-tubocurarine to a myasthenic patient The results justified the attempt

Six hours after the last dose of *d* tubocurarine, and without any neostigmine at all, the patient was moving both arms and legs, and within eighteen hours some of the previously myasthenic muscles were showing even more muscle power than they had ever done before on full neostigmine therapy This was best exemplified by the patient's being able to eat a full breakfast, and even to chew meat, which she had not been able to do since entering hospital Both eyelids remained widely open, and the absence of any myasthenic symptoms persisted for about ten days, after which they began to return gradually At this stage a reduced dosage of neostigmine produced a dramatic response, with the abolition of all myasthenic symptoms This was maintained far longer, and in a fuller degree, than on any of the three previous occasions, where rest alone had been used

Those who witnessed the effects of the curare therapy had no doubt of its benefit These were not maintained indefinitely, but in some patients it should not be impossible to repeat this form of therapy at intervals Nevertheless, treatment of this kind is dangerous and demands constant medical and nursing attention, it should be undertaken only in units experienced in dealing with long-term respiratory paralysis

Griffin et al (1956) reported the successful treatment of a severe case of myasthenia by thymectomy in the presence of respiratory insufficiency

Before the operation the patient was treated by artificial ventilation on an intermittent positive pressure breathing-machine This was continued for thirty five days without any apparent improvement in muscle power despite varying doses of neostigmine To make comparison with the present case easier we emphasise that the ventilating machine was so balanced that the patient made the initial *respiratory* effort himself and the machine then ensured that it was of sufficient volume—i.e, the patient did some of the work At the end of this time he underwent thymectomy, but after the operation, so that he would be spared postoperative distress, respiration was maintained automatically for four days On the sixth postoperative day the patient could breathe easily, and after the ninth day the respirator was not needed again

So striking are some of the resemblances between the case reported by Griffin et al (1956) and the present case that it is impossible not to ask how much of the effects are due to thymectomy and how much to complete rest If complete rest alone can bring about a striking improvement, is this why thymectomy sometimes does so ?

Another remarkable feature of this case is the absence of evidence of "curare sensitivity" even in a patient with extremely severe myasthenia The degree of sensitivity described by various workers varies from 10- to 100 fold, but, as this is probably the first published case in which massive doses have been deliberately administered, the absence of any obvious sensitivity reaction is important Previous tests with both decamethonium and *d*-tubocurarine have shown that it is important, when talking about myasthenic muscle, to differentiate between that which shows clinical weakness and that which does not Those muscles which are already partially paralysed by the myasthenic process naturally become the first to show increased weakness after the injection of *d* tubocurarine On the other hand, it appears that the "apparently unaffected" muscles require a normal dosage level to bring about complete paralysis

These remarks are based on a single case, but the onset of a "myasthenic crisis" is rare and not easily foretold If the circumstances warrant it, there seems to be a reasonable theoretical and practical basis for resting the motor end plates in the manner described. The treatment is hazardous but in ideal conditions is feasible If more such cases were so treated and successful results obtained, the whole value of thymectomy would need to be carefully reviewed.

Summary

A patient with myasthenia gravis who had undergone thymectomy gradually responded less and less to neostigmine Various anticholinesterases were tried, but the patient finally collapsed apparently from excessive drug therapy

Complete withdrawal of all neostigmine like drugs for seven days led, on resumption of therapy, to much improvement This, however, was maintained for only a few days *before* severe myasthenia again became evident

Large doses of *d*-tubocurarine, which provided complete rest for the motor end-plates, led to a dramatic improvement, which was sustained with the aid of reduced neostigmine therapy for nearly three months

The implications underlying this form of treatment are discussed

We want to record our sincere appreciation of the advice and encouragement we received from Mr N R Barrett, under whose care the patient was admitted, and also from Dr H J Anderson and Dr R Kelly We emphasise our admiration for the nursing care by Sister R Stephenson and her staff We are indebted to Dr R S Schwab for the supplies of WIN 8077 This work was carried out with the help of a grant from the endowment fund of St Thomas's Hospital

Preliminary Communication

A pH-ENDORADIOSONDE

As a means of obtaining information from the digestive tract, the use of a small radio transmitter, which the patient can swallow, has two advantages (1) that its presence is not noticed by the patient, and (2) that it provides information that cannot be got in any other way We have recently described a unit which simultaneously transmits pressure and temperature data during its passage through the alimentary canal[1]

In designing a unit that would similarly transmit information about hydrogen-ion concentration, we found that the high impedance of glass electrodes is a disadvantage in connection with the low input impedance of most transistor circuits With the transistors available in this country, we have not been able to construct a small enough endoradiosonde for telemetering pH with a glass electrode

It seems necessary to employ at least two transistors and some sort of high input impedance feedback circuit (e g, the input transistor common collector coupled and another as a radio frequency oscillator) Such endoradiosondes can eventually be constructed, since the active elements in present transistors constitute only a small fraction of their total physical volume The advantages of a glass electrode pH unit are rapid response and high accuracy

The endoradiosonde described here embodies a mechano chemical transducer that changes its dimensions with pH Certain polymers have the property of expansion and contraction with pH changes[2] A copolymer of 20% polyacrylic acid and 80% polyvinyl alcohol gives a reversible change in physical dimensions of 60% for a shift of pH from 3 to 8 After formation by vulcanisation under tension at 80°C for thirty minutes it is insoluble in body-fluids A foil having a dry thickness of 0 05 cm gives an 80% response in twenty minutes, thinner films being faster This copolymer has good mechanical strength, unlike some others having larger expansion and contraction properties Polymethacrylic acid gels, for example, are less suitable as transducers, because they are weak

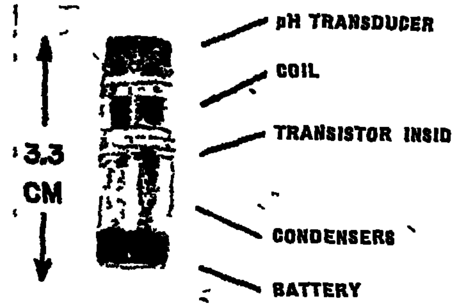

Fig 1—Radiosonde to be swallowed to transmit pH readings during its passage through the gastro intestinal tract. (Actual size) The battery drives the unit continuously for fourteen days

In principle, an osmotic method using the motion of the interface between two opposing dialysing bags would be more sensitive in specified pH ranges and possibly faster But in an experiment in which one bag contained a cellulose derivative soluble in acid, and the other bag contained one soluble in basic solution, the results were less satisfactory than with the copolymer transducer, because of sensitivity to electrolyte concentration

The change of mechanical dimension of the pH sensitive element is transferred to an iron core moving inside a coil constituting the inductance of a transistor oscillator The circuit and construction of this oscillator are similar to that of the unit for measuring pressure and temperature[1] (Since simultaneous temperature measurement was not considered of interest in these preliminary experiments, the mode of operation of the 400 kilocycle oscillator was such as to give non-quenched *oscillation* This was achieved by making the turns ratio of the 500-turn coil 1 10) The change of position of the iron core causes the frequency of the oscillator to shift Thus the pH is telemetered as a frequency modulated signal A limp second diaphragm over another opening in the capsule can render the unit insensitive to pressure changes in the abdomen

The radio signal is picked up by a small loop antenna connected to a standard radio receiver The tuning of the receiver thus gives information of the pH value in the gastro intestinal tract One can track the endoradiosonde through the body with the antenna or, for more accuracy, by X-ray observation

With this unit we have been able to observe the shift in pH from acid in reaction in the stomach towards alkaline in the intestine The slow response time of the copolymer seems not to obviate its use since the speed of pH changes is usually of less importance than the actual final values The accuracy of the unit has not yet been thoroughly investigated in conditions where the electrolyte concentration is much different from that in the calibration liquids

The mechano chemical transducer unit has a length of 0 5 cm and the endoradiosonde with this attached has a total length of 3 3 cm The diameter is 0 9 cm, like that of the unit for pressure and temperature

We are indebted to Dr Birger Blombäck and Dr Victor Mutt for valuable suggestions This work was performed while one of us (R S M) was on leave from the University of California Medical Center as a Guggenheim fellow

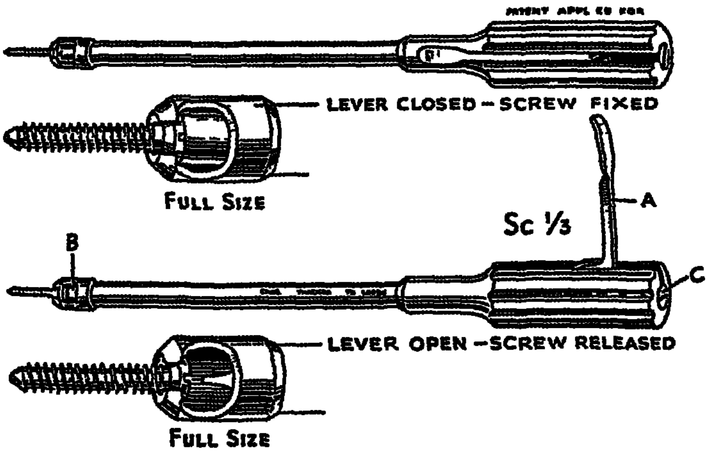
New Inventions

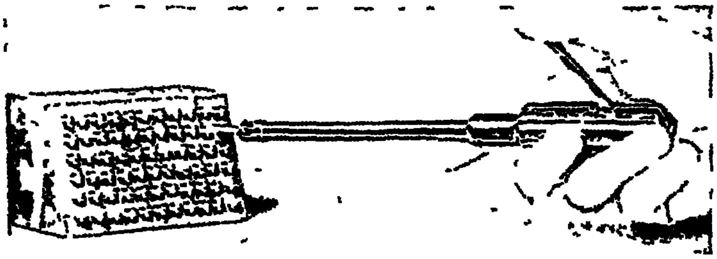
AN IMPROVED SCREWDRIVER

All the self-holding screwdrivers now in use have the disadvantage that they need three hands to load them With the instruments here described, screws can be loaded single-handed and with far greater speed These instruments have been in constant use by myself and other surgeons over the past four years and have proved extremely satisfactory

The screwdriver is an adaption of the Burns pattern, in which the screw-fixing device at the base of the handle has been replaced by a quick-action lever recessed into the handle.

All the usual standard screws, such as Sherman's or Lane's pattern, can be used with this instrument (up to $^{5}/_{32}$ in external diameter of thread with head diameter of $^{5}/_{16}$ in), for the shaped tubular shaft at the distal end has been made to suit a wide variation of shapes of screw head





After the screw has been inserted to the required depth and the screwdriver removed from the screw head, it is possible to drive the screw fully home with the same instrument by merely closing the lever, the end of the tubular shaft is concave externally to accommodate the top of the screw head A special feature is an adjusting screw in the base of the handle This permits the lever to be set to give a firm fixation of the screw head, and once set, it is not necessary to alter it unless a screw with a larger or smaller head is required

All parts of the instruments are made of stainless steel except the handle, which is anodised aluminium The illustration shows the screwdriver being loaded for use

To avoid the difficulties associated with holding the screws in forceps to load them into the screwdriver, it has been found useful to mount them on a solid block of duralumin drilled to receive six screws of each size, ranging from $^{3}/_{8}$ in to 2 in, with the heads protruding When this "screw bank" is loaded, the whole can be easily sterilised by boiling

My thanks are due to Mr A B Hallam of Messrs Thackray, who was responsible for the technical details involved in the construction of these instruments

AN ADAPTABLE WARD BED

A STANDARD WARD BED ADAPTABLE FOR THE UNCONSCIOUS, DISTURBED, OR CHRONIC SICK

This bed was developed at Napsbury Hospital for patients having Sakel's insulin-coma therapy, and has been in use for over a year It is an attempt to meet the ward situation where permanent "cot-beds" are undesirable yet additional facilities may help in nursing the unconscious or restless patient

Insulin treatment involves the patient in a daily period of coma and recovery There are particular risks in precarious metabolism, physical restlessness, and a confused (and often disturbed) mental state Besides appropriate nursing, management entails nasal feeding, intravenous injections, and, at times, electroconvulsive therapy The medical team is often numerically small, and is simultaneously seeking to provide an understanding and careful relationship where purely restrictive physical handling is minimal These specific problems are seen in the insulin unit, but they arise in differing contexts throughout general and mental hospital practice

Fig 1 shows the bed for use as a standard ward bed and the means of fitting the end-pieces to the frame Unlocking and removing the foot-bow and head-piece converts the bed to a trolley, permitting easy access to the patient, particularly from the head—e g, during nasal feeding and electroconvulsive therapy The sliding tray under the head provides a surface for instruments, &c It draws out on either side with stops to prevent over-extension The bed is fitted with a standard wheeling device at the foot, and with individually locking wheels at the head.

Fig 2 shows both padded ends and one padded side in position After removal of the arm-rest, fitting the second padded side completes the cot The padded ends fit and lock in the same way as the foot-bow and head-piece The padded sides run in gutters at either side of the end-pieces The sides and ends are interchangeable between beds, making it possible to use one set of padded ends and sides in conjunction with a number of bed-frames

The cot provides a relatively draught-free space where the necessity for protective handling (which provokes restlessness) is considerably reduced The top of the padded side is 3 ft 8 in above the floor and allows a nurse of somewhat under average height to give nursing attention (other than lifting the patient) without removing the sides With adjacent sides removed, two cots can be fitted together by means of the staples shown, making a protective pen about 6 ft square

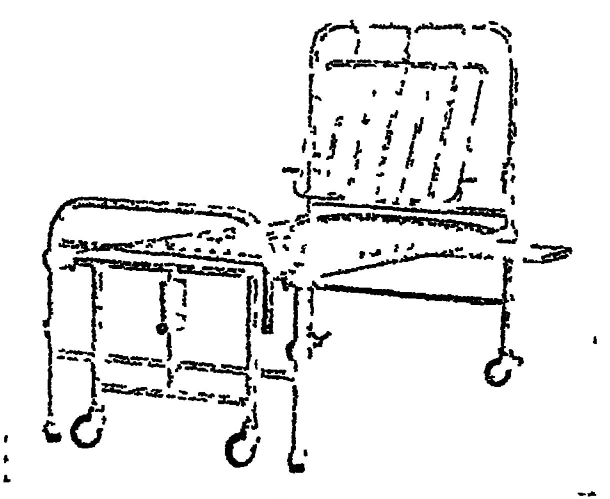

Fig 1

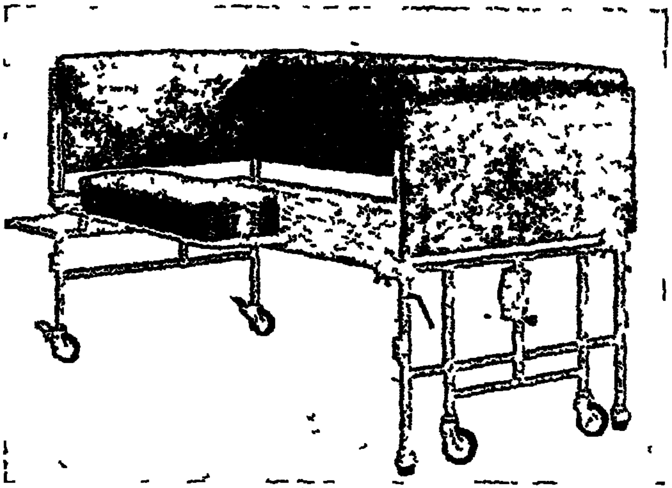

Fig 2

The arm-rest fits by means of pegs into either side of the bed-frame It is padded level with the mattress At the head end there is provision for fitting an aneroid sphygmomanometer, and at the foot a space for a kidney-dish The bed can be tilted by means of a standard tilting frame

I should like to thank the Medical Superintendent and staff at Napsbury Hospital for their help and interest, and acknowledge the proficiency of Messrs S B Whitfield in converting the prototype to a " production model "

Reviews of Books

Practical Forensic Medicine

FRANCIS E CAMPS, M D, *reader in forensic medicine* London Hospital Medical College, W BENTLEY PURCHASE, O B E, M C, M B, barrister at law, coroner for the Royal Household and the county of London London Hutchinson's Medical Publications 1956 Pp 541 75s

IN a preface the authors say that they write " to give medical practitioners and others a fair idea of what the subject comprises " They have not been as comprehensive as this suggests, and that may be fortunate since the subject is, as they remark, already well documented What the book has done is to make a novel and partly successful assault on the established format It starts with A for abortion, accidents, and alcoholic intoxication, and proceeds through the alphabet to W for wounds It then embarks on toxicology, but discards the alphabetical order for a collectanea

There is much that is practical and useful, and the authors' enthusiasm for their subject is apparent Because of this enthusiasm perhaps some sections are handled brilliantly and illustrated well, leaving others either inadequately treated or frankly neglected Thus, identification receives nearly 50 pages of sound and absorbing interest, but perplexing deaths in infancy—an everyday problem—are given a bare 10 and the medicolegal necropsy gets only 2 Barbiturates are generously treated, but there is nothing about the current menace of tranquillisers, and the danger of potentiation by alcohol is summarily dismissed The text is uneven, so that thoughtful and practical passages are followed by material less skilfully handled The English is forthright if not always elegant though most readers will know what is meant by the " time taken for a body to be skeletonised," " any law of local force," or " she was inflated with oxygen "

Nevertheless, this is a refreshingly new approach, which reflects the authors' wide knowledge of legal medicine in a way that the occasional forensic pathologist will find most helpful An index would have avoided the frustration of searching for the information that the book undoubtedly contains, but that is the only really unpractical feature of this attractive work

Physiologic Principles of Surgery

Editors L M ZIMMERMAN, M D, professor and chairman of the department of surgery, Chicago Medical School, R LEVINE, M D, chairman, department of medicine, and director, department of metabolic and endocrine research, Medical Research Institute, Michael Reese Hospital Philadelphia and London W B Saunders 1957 Pp 988 *105s*

ALTHOUGH its main roots remain in anatomy and pathology, modern surgical thought and practice is increasingly concerned with disturbances of function, as seen both in disease processes and as a result of surgical procedures themselves Consideration of such problems must be based on a clear appreciation of the physiology of the systems involved, and this book is intended as an " authoritative statement of the current status of the various physiologic problems in surgery " In this intention it largely succeeds

Separate sections, each written by an expert, deal with the various basic, general problems, such as hæmorrhage, tissue transplantation, and pain, and all the more specialised problems arising in each and every branch of surgery The extent to which purely clinical considerations are emphasised varies from section to section, but each is essentially a study in applied physiology The book contains a vast amount of valuable detailed information not to be found in any other single volume, and deals fully with the great range of subjects now covered by modern surgical research Each section contains full references to the subject concerned

Focusing attention on fundamental physiological processes, this volume is a valuable addition to surgical literature It is of particular interest to postgraduate students and those engaged in surgical research work, but practising surgeons should find here much of interest and value to them

Family and Kinship in East London

A Survey by the Institute of Community Studies MICHAEL YOUNG and PETER WILLMOTT London Routledge & Kegan Paul 1957 Pp 232 25s

THE first of a series of reports to be issued by the Institute of Community Studies, this survey deals with the effect on family life of the new housing estates which have been built in their hundreds since the war The first part of the book studies the close kinship, the intimate family and living conditions in Bethnal Green, with Mum always close at hand The second part discusses the effects of moving to a new housing-estate, Greenleigh, a few miles away, where the young family is very much on its own and where the common complaint is that other residents are unfriendly and snobbish

The authors conclude that most residents in Bethnal Green, tied to the district by time and by a lasting attachment to their families, wish to continue to live in the East End They believe that the authorities should do more than they are at present doing to enable them to continue to do so, rather than insisting that more thousands should migrate beyond the city, and that if the authorities regard community spirit as an asset worth preserving, they should build new houses around the social groups to which the people already belong

---

Treves' Surgical Applied Anatomy (13th ed London Cassell 1957 Pp 591 30*s*) —The first edition of this book appeared in 1883, so it is the oldest textbook of surgical anatomy in English still in current use It is a tribute to the practical wisdom and literary skill of the original author and of subsequent editors that it should also be one of the best Prof Lambert Rogers is responsible for the latest edition It is more than a safe guide through the finals with its wealth of clinical information, it fulfils the wish, expressed in the preface to the first edition that " it should make the dry bones live " This edition is unlikely to be the last

THE LANCET

LONDON SATURDAY, JUNE 15, 1957

Polyarteritis Nodosa

CORTISONE and corticotrophin were the first agents reported to have a convincing effect on polyarteritis nodosa.[1 2] But the important question whether cortisone prolongs survival remained unanswered, and a panel of the Medical Research Council has sought to resolve this by a controlled therapeutic trial. The task presented serious difficulties and the outcome has been somewhat disappointing. The panel rightly decided that it would be ethically wrong to adopt the procedure (used in therapeutic trials in less lethal diseases) in which selected patients are allocated at random to treated and control groups. The only alternative was to treat all patients fulfilling the criteria for diagnosis, and to compare their fates with those of patients selected retrospectively on the same criteria. The scarcity of cases made it necessary to collate observations made by a large number of physicians in many hospitals. Complete suppression of the disease was the goal, and the dosage of cortisone was limited only by the need to avoid intolerable side-effects. The analysis of the results of the first year of the trial[3] is based on 17 cases in which the diagnosis was made and treatment started in 1950. The untreated control series consisted of 19 patients, from the same hospitals, in whom the disease had started between 1941 and 1950. The two groups were similar in all major respects, with the important exception that hypertension was very much more common in the untreated group (42% at the time of diagnostic biopsy) than in the treated group (6%). The prognosis is much worse in hypertensive patients, and it is not surprising that only 7 of the 19 untreated patients were still alive a year after diagnosis; of the 17 treated patients, 14 were still alive. Thus the untreated group failed to provide a satisfactory control for the treated group, and no firm conclusion could be reached about the efficacy of cortisone in prolonging life. It was concluded that "assessment of therapeutic activity by the use of retrospective controls is an inherently fallacious method and no substitute for the strictly controlled clinical trial."

In patients severely ill with polyarteritis nodosa the initial effects of cortisone were always definite and often dramatic. Within two or three days fever abated, appetite and well-being improved, and pains in joints and muscles decreased. But complete clinical remission and maintenance of a normal erythrocyte-sedimentation rate were rarely achieved—for example, in only 3 of the 15 survivors during the seventh and eighth months of treatment. But the dosage used varied, and truly suppressive doses (which may be as high as 300–500 mg. daily) were not always given. At such high doses, gross features of Cushing's syndrome appeared, and in one patient a gastric ulcer perforated; in a second patient, taking 300 mg. of cortisone daily, a duodenal ulcer developed, but healed without any change in the dosage. During treatment, the blood-pressure rose in the sole hypertensive patient, and 5 other patients became hypertensive —1 died with malignant hypertension. It was impossible to decide whether the increase in pressure in these patients was due to specific renal lesions (for which there was evidence in 4) or to cortisone.

The collection of untreated control cases for the M.R.C. panel was undertaken by Dr. G. A. ROSE, and this part of the investigation yielded some important data on the natural history of polyarteritis nodosa, gleaned from 104 case-records. In their analysis ROSE and SPENCER[4] distinguished a group of cases with involvement of the lungs and other special features. Indeed, the presence or absence of lung lesions seemed to be a more useful basis for classification than the size of vessels involved or the separate types of vasculitis distinguished by ZEEK.[5] The features common to the 14 patients with pulmonary polyarteritis (and much less common in the remainder) included a respiratory illness initiating the disease, the presence in various viscera of unusual necrotising and granulomatous lesions, and mucosal ulceration of the alimentary tract and trachea. In a further 18 cases, pulmonary arteritis was not seen (necropsy material was inadequate in some), but the presence of the remaining special features justified their inclusion in the same "lung-involvement" group. The granulomatous lesions in these cases were found in sites remote from arteries. High eosinophil-counts in the blood (1500 or more cells per c.mm.) and polyarterial lesions containing giant cells or many eosinophils were commoner in this group, and nasal and middle-ear granulomas were never seen when the lungs were not involved. The initial respiratory illness was classed as bronchitic, pneumonic, or asthmatic. Even at this early stage it was often clear that the illness was not a straightforward one. Patients with a bronchitic illness often lost weight steadily and general weakness became prominent. Pneumonic cases ran a rather chronic course, with productive cough, pleuritic pain, and hæmoptysis; antibiotics were ineffective. Asthmatic attacks were frequent and severe, usually with eosinophilia in the peripheral blood. In two-thirds of these cases, over a year elapsed before systemic polyarteritis nodosa became manifest. The onset of the respiratory phase was often insidious, but in the systemic phase deterioration was rapid and the course shorter than it was when there was no initial involvement of the lungs. This rapid progression of the systemic phase may explain why patients with lung involvement are less prone to hypertension than those with more slowly progressive disease without respiratory features, though an apparently identical glomerulitis was seen in both groups.

[5] Zeek, P M *Amer J clin Path* 1952, 22 777

Small series of polyarteritis nodosa with lesions in the lungs have been reported in the past, but the other distinctive features of such cases have not always been appreciated **CHURG** and **STRAUSS** [6] described fully the non-arterial granulomas present in 13 out of 14 cases with asthma, eosinophilia, and polyarteritis, and they gave the name "allergic granulomatosis and angiitis" to what they considered to be a syndrome distinct from polyarteritis nodosa It seems clear, however, that granulomatous lesions, though restricted to cases with involvement of the lungs, are not necessarily associated with asthma **ZEEK** and her colleagues [5 7] distinguished "*hypersensitivity angiitis*" from classical polyarteritis nodosa, but **ROSE** and **SPENCER** found no cases in their series which fulfilled the criteria for this syndrome

ROSE and **SPENCER** extracted from their case-records information which might form the basis of a future specific inquiry into the ætiology of polyarteritis nodosa Attempts have been made in the past to implicate various drugs, but the symptoms which prompt the giving of a drug may be those of early polyarteritis, or of an infection which is the true cause of the ensuing vascular disease Perhaps the most suggestive evidence was that which linked polyarteritis nodosa with *respiratory infections* (especially those due to β-hæmolytic streptococci) and their treatment with sulphonamides In nearly all the reported cases in which an association between a sulphonamide drug and polyarteritis has been suspected, the drug has been given for a respiratory infection The sputum had been cultured in 22 cases, and in 5 of these β hæmolytic streptococci were isolated—a finding which would be unexpected in uncomplicated bronchitis Moreover, 12 5% of the patients had active rheumatic fever or a history of an attack—a link with the streptococcus which others have noticed [8 9] Evidence against a drug was clearest in the case of thiouracil and other antithyroid drugs, but it seemed that thiouracil polyarteritis might differ from ordinary polyarteritis nodosa **ROSE** and **SPENCER** make a plea for including in the investigation of cases of polyarteritis nodosa an accurate account of any recent drug administration and an early search for cultural or serological evidence of recent β-hæmolytic streptococcal infection As in patients with recurrent rheumatic fever, prompt treatment of any acute throat infection may well be important in polyarteritis nodosa

ROSE and **SPENCER** believe that the hypertension is a sequel of renal polyarteritis or glomerulitis, but that the arterial pressure rises only during the healing stages of these lesions More than half the patients with adequate records of arterial pressure had normal readings throughout their illness and at necropsy tended to have glomerular lesions of recent origin Patients who were hypertensive throughout, or became hypertensive, usually had chronic glomerulitis or healed renal polyarteritis Rises in arterial pressure were found only after proteinuria or hæmaturia had developed **ROSE** and **SPENCER** conclude that the hypertension is nearly always a result of the polyarteritis nodosa and not a precursor

The Endocrine Complex

WITH some reason the anterior pituitary has been allotted a prominent position in the hierarchy of endocrine glands Thus, it is believed to form at least six hormones—thyrotrophic (T S H), adrenocorticotrophic (A C T H , corticotrophin), follicle-stimulating (F S H), luteotropic (L H), mammotrophic (prolactin), and growth (G H) Five of these substances are known to be directly concerned in regulating other endocrine glands, and the sixth (G H) appears to be important for the growth and maintenance of all tissues The parathyroids and thymus seem to be *independent* of the anterior pituitary, though their actions are obviously modified by its absence, owing to a general disturbance of all functions Intensive research has partly elucidated the functions of the endocrines and, because of this and the availability of hormones such as cortisone, it has become feasible to remove, for therapeutic purposes, apparently normal pituitary glands This operation has underlined the urgent need for yet more information about endocrine functions and interconnections, partly in order to determine when the operation will be beneficial, and partly to obviate the need for this heroic and blunderbuss method—hypophysectomy offers only temporary respite from the progress of cancer of the breast and is useless against cancer at many other sites More information is needed, too, in order to help patients with so-called simple endocrine disorders

The rationale of hypophysectomy for breast cancer lies in the endocrine control of mammary growth, about which *there is now agreement on general* principles [1–4] Observations on animals after removal of one or more of the anterior pituitary, adrenals, and ovaries has shown that moderate doses of œstrogens induce growth of the mammary ducts, and that œstrogen plus progesterone given in a ratio of about 1 30 induces lobular-alveolar growth, but that œstrogen and progesterone are ineffective in the absence of the anterior pituitary In unoperated animals a combination of œstrogen and prolactin leads to lobular-alveolar growth since prolactin is itself luteotrophic, and therefore promotes the production of progesterone If to an otherwise normal animal enough œstrogen is given to cause pseudo pregnancy, again mammary development is seen because the œstrogen stimulates the anterior pituitary which releases prolactin, and this stimulates the release of progesterone, so that once more these three substances are present Thus, œstrogen and progesterone from the ovary and prolactin from the anterior pituitary are necessary for the development of the mammary glands The prolactin has a dual rôle in stimulating the production of progesterone from the corpus luteum of the ovary, and in exerting some other and more directly growth-promoting function, since œstrogen and progesterone together are inadequate It is not known whether in its non-luteotrophic activity prolactin directly stimulates the mammary glands or influences metabolic processes in a general way, the former is a possibility since in an animal

previously treated with œstrogen and progesterone prolactin injected into one milk duct has a well-localised action[3] Mammary growth can be induced even in the absence of adrenal cortical tissue, but, not surprisingly, growth is more nearly normal if the tissues receive their proper quota of both adrenal steroids and G H In the absence of the ovaries the adrenal cortex produces ovarian hormones, so ovariectomy alone will not deprive a malignant breast growth of its needed hormones for more than a short time The exact part played by G H is still little understood[5] All these observations point to the importance of the anterior pituitary Some recent work[6] suggests that the posterior lobe, too, may have to be drawn in, since there is evidence that one of its hormones—oxytocin—causes the release of prolactin In addition, the thyroid has to be considered owing to the observation that patients with hypothyroidism are more prone than patients with hyperthyroidism to cancer of the breast and genital organs This may be compared with the observation of TRENTIN et al[7] that in rats after thyroidectomy the mammary glands are particularly sensitive to the effects of œstrogen and progesterone From all this it is clear that the actions of a hormone cannot be considered in isolation, but only in the context of other hormones

In the hitherto vain attempt to establish which patients will benefit from hypophysectomy, several interesting facts have come to light—for instance, that the excretion of œstrogens continues after ovariectomy and is not necessarily abolished by subsequent adrenalectomy and even, in some cases, hypophysectomy[8] This means either that the so-called hormone-independent growths are perhaps not really independent, or that in some people there is accessory anterior pituitary tissue which is active throughout life or becomes so after removal of the anterior lobe Anatomical evidence of accessory tissue was described by BOYD,[9] who examined the region of the roof of the nasopharynx, from which the anterior lobe develops embryologically, and found groups of cells resembling differentiated anterior-lobe cells Another point of interest is the rate of atrophy of those endocrines which depend largely on anterior-lobe hormones for their activity thus, vaginal smears suggest that the ovaries atrophy in about 4 weeks, urinary excretion of gonadotrophin ceases in 2 weeks to 3 months, and clinical myxœdema appears in 1 to 6 months[10] This is roughly what might have been expected from observations in other species

The object of hypophysectomy in the treatment of cancer is to reduce the output of G H, corticotrophin, and gonadotrophins RUSSELL[11] suggested that this object might be achieved no less certainly by low-stalk section, which is much simpler than total removal of the gland The arterial supply of the anterior lobe of the pituitary is interesting in that all the capillaries are second-group capillaries arising from vessels which are derived from a mass of first-group capillaries lying either in the hypothalamus or in the tissue of nervous origin low down in the pituitary stalk[12] A mid-stalk section results in reduction of anterior-lobe volume by as much as 68–83%,[13] but this leaves more than enough pituitary tissue to maintain other glands in working condition[14] In two of the three clinical cases considered by RUSSELL, low-stalk section led to complete necrosis of the anterior lobe, presumably because even the most ventral supply vessels had been divided Experience alone can show whether this simpler operation is adequate

Besides the interactions of the endocrine system already considered, some others are well recognised, such as the control of T S H and corticotrophin release by the activity induced in the target organs, thus, the amount of circulating adrenal steroids and thyroxine is directly related to the amount of corticotrophin and T S H liberated Other less well-known relationships are now being found It has been noted clinically and histologically[15] that absence of adrenal cortical steroids may be accompanied by thyroid hypertrophy Recently it has been shown that there is sometimes an inverse relationship between corticotrophin and T S H release[16] Certain types of stress, surgical trauma, or hæmorrhage, which are known to cause the release of corticotrophin, inhibit the rate of release of ^{131}I from the thyroid—i e, less thyroid hormone is liberated This inhibition occurs even when the thyroid gland is denervated and also after adrenalectomy, and must, therefore, depend on central nervous system influences, and the likeliest route by which these can affect the thyroid is by alterations in secretion of T S H from the anterior pituitary[16] A similar inhibition occurs on administration of fairly large doses of corticotrophin and cortisone On the other hand, in Addison's disease and in adrenalectomised animals small doses of cortisone may increase thyroid activity[17] Though its mechanism is unknown, this reversed action is understandable since in the patient with Addison's disease thyroid function is below par owing to the absence of a substance necessary for normal cell activity, whereas the situation is quite different when the concentration of adrenal steroids is raised above normal in a healthy animal

Events in the central nervous system profoundly affect endocrine activity—usually by means of hormones liberated from the anterior pituitary, and rarely by direct nerve stimuli as in the adrenal medulla It is generally believed that the anterior lobe has no secreto-motor supply and must therefore be influenced by hormones Some of these, such as adrenal steroids and thyroxine, come from the peripheral organs, but what, if anything,[18] is released from the central nervous system to affect anterior-lobe activity is unknown A vascular path for such a substance exists in the double capillary system already mentioned, the first part of which lies in nervous tissue and leads via the so called portal vessels to the second part in the substance of the anterior lobe It is clear that the proper continuity of this vascular link is important for some aspects of pituitary activity For example, if this path is cut or the anterior lobe transplanted to another site, eosinopenia still follows stimuli which can be classed as systemic, but not those which can be called neurotropic[19] Also, in animals the weights of the ovaries are directly correlated with the presence of the vascular connections between the hypothalamus and the anterior lobe[19] With regard to the thyroid

[18] Thomson, A P D, Zuckerman, S *Nature, Lond* 1953, 171 970

> "it may be concluded that the pituitary divorced from anatomical connection with the hypothalamus retains a residuum of autonomous activity with regard to the secretion of the thyrotrophic hormone and that this activity can be inhibited in an apparently normal way by a raised blood level of thyroid hormone and by the stress of physical trauma The function of the hypothalamus in relation to T S H secretion seems to be to *maintain* the normal rate of secretion and to *modify* this rate of release in response to stimuli acting through the central nervous system "[16]

That is to say, the activity of the anterior lobe is modified by both the central nervous system and the blood concentration of thyroid hormone Whatever view is held of the mode of control of the anterior pituitary, it is clear that even a successful graft does not function as satisfactorily as the gland in its proper position in relation to the hypothalamus

The last aspect of the problem is the one about which we know the least, but on which much work is now being done—that is, the action of the various hormones on the nervous system[20] That hormones do affect the nervous system is evident from cases of hyperthyroidism or hypothyroidism, premenstrual tension, and other disorders The possible modes of action are many, from changes in activity of one or more cellular enzyme systems and changes in intracellular and extracellular electrolytes and water concentration to alterations in ease of synaptic transmission between some types or groups of neurones whose activity specifically affects the anterior lobe That man can live without an interior lobe but with a modicum of substitution therapy shows that for all his complexity he has remarkable powers of adaptation

CIGARETTE-SMOKING AND RESPIRATORY DISEASE

Doll and Hill[1] found an association between smoking and lung cancer, Lowe[2] one between smoking and respiratory tuberculosis, and Leese[3] one between smoking and chronic bronchitis Edwards[4] now describes an analysis of the relationship between cigarette-smoking and respiratory disease, based mainly on the data compiled by these workers The association between cigarette smoking and cancer of the lung was confirmed Adenocarcinoma, however, did not seem to be commoner in smokers than in non smokers, and, although smoking seemed to increase to a comparable extent the liability of men and women to oat cell carcinoma, it seemed much less liable to provoke squamous carcinoma in women Assuming that the smoking habits of Lowe's controls represented those of the general population, Edwards calculated that 84% of cases of lung cancer in men and 34% of cases in women are related to smoking If this estimate is correct, 12,000 men and 770 women died of smoker's cancer in 1954 The death-rate from lung cancer is not so high in New Zealand as in this country despite proportionately heavier smoking there[5], but the difference may be accounted for by the greater pollution of the atmosphere in Britain, for there is evidence[6] that atmospheric pollution by itself increases the liability to lung cancer, and that the carcinogenic effects of smoking and atmospheric pollution are additive With respect to respiratory tuberculosis, Edwards estimated that at least a third, and probably more than half, of the notifications in men over 30 years of age and almost a quarter of the notifications in women over 30 years of age were attributable to smoking

According to Edwards's calculations concerning lung cancer and tuberculosis, the damage done per cigarette per day tends to decrease with the number smoked Contrary to what might be expected, therefore, it seems to be less than twice as dangerous (not more than twice as dangerous) to smoke thirty cigarettes a day than to smoke fifteen a day or, to put it in another way, there would be more lung cancer and tuberculosis in a population if all its members smoked fifteen cigarettes a day than there would be if half its members smoked thirty a day and the other half did not smoke at all

The importance of the rôle of smoking in the ætiology of chronic bronchitis was harder to estimate, but Edwards considers that, although atmospheric pollution is probably the most important single causal agent, smoking is a necessary additional factor in most cases In chronic bronchitis, the damage done per cigarette per day seemed to increase with the number smoked Edwards concluded that the total number of deaths from the three major respiratory diseases in Britain—lung cancer, tuberculosis, and chronic bronchitis—would be halved in the absence of cigarette smoking

These calculations indicate the striking improvement in the public health that might be expected if cigarette smokers were persuaded to give up this habit—and if young people were persuaded not to engage in it

SURGERY IN SPINAL TUBERCULOSIS

WHICHEVER part of the skeleton it attacks, tuberculosis places the surgeon in a quandary Instinct prompts him to deal with the lesions operatively, by principles sound for other diseases—to evacuate pus where it has formed, to remove necrotic tissue, and to obliterate the defects resulting from suppuration In the past he has been restrained, when contemplating such intervention, by two very real fears It was always possible that by operation he might *disseminate* the very infection he strove to eradicate, or a secondary infection, gaining access through his incision, might produce a worse state than the initial one Only twelve years ago, Dickson[1] justifiably warned his colleagues that even "introducing a drainage tube into a tuberculous abscess makes certain a *draining* sinus will form, which will become secondarily infected and will probably never heal It has been truly said that draining a tuberculous abscess frequently signs a patient's death warrant" At no site have these risks seemed graver than the spine. Abscesses there have nevertheless been attacked surgically Treves, in 1884, described an operation in which diseased lumbar vertebræ were exposed by a paravertebral incision, any bony sequestra found were removed, and at the same time a drainage-tube was passed through the psoas abscess, emerging some distance from the involved vertebræ But such procedures were seldom undertaken, for too often they ended in disaster

---

[1] Dickson F D *In* Bancroft, F W, Murray, G R Surgical Treatment of the Musculo Skeletal System Philadelphia 1945

Today, with chemotherapy, surgery for all tuberculous lesions is permissible more often, and earlier, than has been the case hitherto Wilkinson[2] emphasises how destructive the disease can be in young children when it affects the lower thoracic vertebræ Conscious of the inhibiting effect of pus on bone repair, and of the inaccessibility of necrotic areas to circulating antibiotics, he has operated on such patients within a month or two of the disease being diagnosed Foci in the vertebral bodies are curetted out and packed with bone chips, and abscesses are evacuated With adult patients he proceeds a little more slowly, watching them for some three or four months and being prepared then to operate if bone destruction is continuing, in such cases an abscess should be suspected The complications have been relatively trivial—short-lived sinuses and, occasionally, pleural effusions, they have not included miliary spread In the United States the surgery of spinal tuberculosis has recently been carried a stage further Weinberg[3] holds that permanent healing may not follow incision and drainage alone An abscess tract may be tortuous or constricted, and may give rise to irregular diverticula which cannot be satisfactorily evacuated He has removed the abscess sac in toto by extensive paravertebral and retroperitoneal dissection, proceeding into and beyond the femoral ring if necessary In 11 cases thus treated there has been only 1 recurrence, and no death But the operation is formidable

In the management of paraplegic patients, too, surgery is coming to play a more important part Hitherto there have been strong deterrents First, exposure of the spinal cord by a posterior route may remove the only stable portion of a crumbling vertebral segment and may aggravate existing deformity and cord damage, and secondly the lesion itself may prove to be due to some condition—for instance, thrombosis—not amenable to surgical relief These deterrents, plus the fact that spontaneous recovery is not rare, have in the past dictated a very conservative approach to Pott's paraplegia

In a timely monograph Griffiths, Seddon, and Roaf[4] attack this "peculiar and quite unscientific complacency" They point out that, in the largest and most recent reported series of conservatively treated paraplegic cases, a quarter of the patients died and less than half made a worth-while recovery They lay down a list of indications for exploration, emphasising that cases of rapid onset, severe degree, or persistent character should always be operated on The causal focus is usually anterior to the theca, and it is now appreciated that laminectomy, and even costo transversectomy, will not expose a lesion so situated Griffiths et al have found the anterolateral approach of Alexander[5] and Dott[6] to be the most useful In this the front of the theca is approached from the side of the vertebra, three or four ribs at the affected level are resected at their posterior ends, and the appropriate transverse processes removed, the backs of the diseased vertebræ and the pedicles well anterior to the posterior joints can then be nibbled away, an excellent view of the theca is thus obtained, but the lateral stability of the spine is preserved Perhaps the most important point which emerges from this study of Pott's paraplegia is the susceptibility of the condition found at operation to surgical treatment The pachymeningitis and cord œdema, which loomed so large in earlier accounts, are discounted as causes of paralysis In each of 49 cases explored, Griffiths et al found and removed a mechanical cause of compression—sequestrum, bony ridge, or abscess—and in 36 cases a good recovery ensued They sound a warning note when they point out that "the operation is never easy, always dangerous, and often frightening" It is obviously not one for the occasional spinal surgeon Nevertheless we may expect to see paraplegic patients more commonly operated on and more rapidly and more commonly restored to health as a result of this encouraging report

CORONARY-ARTERY DISEASE

IN November, 1955, the World Health Organisation assembled a study group on atherosclerosis and ischæmic heart disease Their report[1] is a clear statement of established knowledge, and it also outlines ways in which this knowledge can be extended and applied

The need to distinguish between ischæmic heart-disease and atherosclerosis is rightly emphasised though the processes concerned in the two conditions are usually concurrent, they may be independent Proper diagnostic criteria are important both at the bedside and in the post mortem room, and the group propose that representative pathologists should meet and suggest uniform methods for examining the coronary arteries and for recording their results Uniformity in standards for clinical diagnosis would be difficult to bring about, yet it is hard to see how confusion can be avoided unless there is uniformity in the use of diagnostic terms

The factors thought to be concerned in the genesis of both ischæmic heart disease and atherosclerosis may be divided into the constitutional and the environmental Among the constitutional factors, the group think that heredity, sex, and specific inborn metabolic disorders (e g, familial hypercholesterolæmia) need further study Diet, reduced physical activity, and the stress, strain, and mental tension of modern life are three environmental factors which the group regard as important, and they discuss alcohol and tobacco, infections, and associated arterial hypertension as possible contributory agents Their account of the principal epidemiological, laboratory, and clinical findings which implicate these factors is admirable Their recommendations for research, on the other hand, are much less explicit and helpful, and this is a pity because vague generalisations can provide an umbrella covering much waste of time and money on unsuitable investigations

An appendix addressed to the public-health services shows the need for epidemiological and statistical studies, particularly in areas where the inhabitants differ greatly in their economic status for such work to be profitable, an essential is uniformity in procedures, nomenclature, and the handling and analysis of data By way of prevention, all the public health doctor has to offer at present is the advice of moderation This can be directed at men and women who take too much food, too much alcohol, too many cigarettes, or not enough physical activity, or who "over indulge in many activities" Such advice has, of course, been given by generations of wise physicians, and neglected by generations of careless patients It is still sound, but is by no means easily put over by public-health departments, whose nurses are better at showing mothers how to raise a family than at teaching business executives how to change their manner of life In point of fact, the techniques of this kind of health education have not yet been worked out, and the study group do not help much when they say that the "health officer can determine the type and appropriate-ness of educational activities, in collaboration with practising physicians, official and voluntary health associations, and interested community agencies" With prevention as with research, they point clearly to the broad highway but give little guidance through the lanes and byways which lead up to it Appreciation of their excellent report is tempered only by regret that they were not kept together long enough to go into more detail

SULPHUR AND SEBORRHŒIC DERMATITIS

THE rate and route by which substances pass through the skin from the exterior have been studied by means of radioactive isotopes The best known of these investigations concerned the vesicant war gases Scott[1] has lately investigated the beneficial effect of sulphur applied locally in various dermatoses

There is no doubt that sulphur is absorbed through the skin, since local application can lead to sulphæmoglobinæmia It has been thought that it penetrates as a sulphide, but that its therapeutic effects follow its modification into $H_2S_5O_6$ For this reason, treatment with polythionic acids was introduced, but it does not seem to have been widely successful Sulphur is normally present in the skin as sulphydryl and disulphide groups probably representing sulphur-containing amino-acids, particularly in the proteins of enzyme systems It is also represented in the intercellular ground-substance as an ingredient of mucopolysaccharides Disturbances in local sulphur metabolism may therefore have pathological consequences A striking example is blistering from the poisoning of enzyme systems by heavy metals and its relief by offering alternative thiol groups in the form of dimercaprol (BAL)

Scott has tackled the problem using radioactive sulphur by autoradiography She applied ^{35}S to the skin of healthy subjects and took biopsy specimens at fixed intervals Having established the normal rate and route of absorption, she repeated these studies in cases of seborrhœic dermatitis, acne vulgaris, psoriasis, and a few other disorders

In normal skin, absorption began two hours after application, and the element had completely crossed the epidermis within eight hours With many substances there is preferential absorption through the pilosebaceous follicles, but this was not observed with sulphur After sixteen hours most of the sulphur was in the dermis, little remaining in the epidermal layers Within twenty-four hours it had disappeared, and since it did not recross the epidermis it must have been taken up systemically There was no microscopical evidence that the sulphur was handled by the epidermal cells, its path being apparently intercellular

In seborrhœic dermatitis, penetration began within half an hour of the application of radioactive sulphur, which accumulated in the mid epidermis during the first twenty-two hours, none going into the basal layers or beyond Thereafter the sulphur migrated outwards, and during its residence in the epidermis it was apparently attached to cells In acne there was normal penetration of the epidermis, but concentration and persistence occurred in the pilosebaceous follicles from which it did not appear to be absorbed into the dermis, but the reverse is inferred from the "corresponding dermal accumulations of sulphur adjacent to the glands" In psoriasis sulphur penetrated to the basal layer within four hours, and much greater quantities were absorbed than in normal skin Little entered the dermis and most was shed outwards through the epidermis Again, there appeared to be intracellular localisation of ^{35}S In the miscellaneous group, including contact dermatitis, there was little departure from normal apart from accelerated passage through the epidermis Lichenification, however, was associated with a generally slower rate of absorption With improvement of seborrhœic and psoriatic lesions the behaviour of sulphur reverted to normal Scott suggests that sulphur applied to the skin in these dermatoses may have some significant biological action, such as involvement in the intracellular systems involving SS and SH groups

We do not yet know whether the behaviour of sulphur in these cases is peculiar to that element Would it not be reasonable to repeat the study with some element foreign to the skin? This might dispose of the suspicion that all that the tracer is doing is to reveal the dynamics of the epidermis Two factors should be considered first, the influence of œdema, and secondly the rate of cell division and outward migration Œdema might favour absorption, and Scott herself observed that erythema produced with ultraviolet light caused sulphur to penetrate much more rapidly Cell division would influence outward transference of the element, thus in lichenification, with increased cell multiplication, there is diminished absorption Combinations of different degrees of the two factors would cause varied patterns of "absorption"

Scott's findings, if substantiated, will necessitate the recognition of seborrhœic dermatitis as a genuine entity by those who regard it as merely one manifestation of eczema, and will call for further biochemical studies of this disease

EXTERNAL PANCREATIC FISTULA AFTER GASTRECTOMY

THE pancreas has been likened to a powder keg which responds capriciously to handling The dangers of operating on the pancreas, even for biopsy, are well known, and experienced surgeons are aware of the hazard of injuring this gland during subtotal gastrectomy Millbourn[1] has shown that pancreatic damage, judged by a significant increase of urinary diastase, was present in 13 of 147 patients after gastric resection, but evidence of severe pancreatic involvement was clinically manifest in only 5, of whom 2 died Both he and Warren[2] have discussed modifications in the technique of gastric resection to avoid such catastrophes

When external pancreatic fistula follows operation on the stomach one of the major pancreatic ducts has usually been injured, either as it lay in the floor of a penetrating ulcer when the ulcer was being dissected off the pancreas or when the duodenal stump was mobilised Usually these fistulæ are incomplete and close spontaneously, since in gastric resection for duodenal ulcer the duct of Santorini, being the more vulnerable, is the most commonly injured, and only rarely, as in one of Millbourn's fatal cases, does this duct exclusively drain the larger part of the pancreas

Sinclair[3] describes an external fistula which persisted, after Polya gastrectomy for duodenal ulcer, for ten weeks, during which he studied pancreatic function The pancreas responded poorly to intravenous secretin and pancreozymin, and, though the dosage of these hormonal extracts was small, this suggests that the function of the gland may have been impaired by duct injury at operation—a suggestion supported by the radiographic evidence of a dilated duct system and by the increase in serum or urinary enzymes found in the same circumstances in other cases Moreover after the Polya gastrectomy the low acidity of the chyme deviated from the duodenum and passed directly into the upper jejunum may have modified the response of the pancreas to physiological stimulants such as food Such variable factors as these may explain conflicting reports on external pancreatic fistulæ in man

When damage of a pancreatic duct or the common bile duct is recognised at operation the duct should be

sutured at once to the duodenum or jejunum, opposing mucosa to mucosa (A severed duct of Santorini which can be shown to connect with the main pancreatic duct may be ligatured with safety) When injury to a duct at operation is not detected at the time, it usually declares itself on the second postoperative day by upper-abdominal pain and pyrexia associated with raised serum or urinary amylase levels If division of the duct of Wirsung is suspected the region of the head of the pancreas should be drained and repair of the duct deferred to a more propitious time Otherwise the patient is treated as if he had acute pancreatitis, with continuous aspiration of the gastric remnant and intravenous administration of fluids and electrolytes, if necessary glucose and protein hydrolysates can be given intravenously, and the use of broad-spectrum antibiotics, though these do not pass into pancreatic juice, is justified at this stage In desperate circumstances a jejunostomy to feed the patient may be life saving, though in Sinclair's patient glucose given directly into the jejunum by tube stimulated the flow of pancreatic juice

Should an external fistula follow, this will usually close spontaneously, and meanwhile conservative treatment is directed towards protecting the skin from digestion, maintaining fluid and electrolyte balance, and if necessary replacing lost pancreatic enzymes It is doubtful whether measures usually recommended to depress the external pancreatic secretion, in order to encourage the fistula to close, are of much value [4] When food is taken by mouth a bland mixed diet is probably best, since fat and protein produce less pancreatic juice than carbohydrate Ephedrine, atropine, and propantheline ('Probanthine') have all been recommended to reduce the volume of secretion Conservative measures should be persisted in for several months, but if the fistula has not closed after six months, or if closure leads to pain, vomiting, or cyst formation, then operation should be considered The Lahey operation,[5] which consists in implanting the fistulous track into the jejunum, occasionally fails because the fistulous duct, having no epithelium, closes and pancreatic cysts form In these rare circumstances some other manœuvre, such as excision of the distal part of the pancreas together with the origin of the fistula,[6 7] may be necessary A possible alternative is a retrograde or caudal pancreatico jejunostomy, as performed by DuVal [8] in cases of chronic relapsing pancreatitis

CUTANEOUS URETEROSTOMY

URINARY diversion by implanting the divided ends of the ureters into the abdominal wall has never been widely favoured, for it requires a urinary collecting apparatus On the other hand, with this method there is less risk of biochemical imbalance and ascending pyelonephritis than with ureterosigmoidostomy, and in certain cases, particularly where only one functioning kidney remains, its adoption may be advisable Standard techniques, however, commonly involve an indwelling ureteral catheter, which may predispose to the very hazard that the method is supposed to avert—namely, stenosis of the ureteral stump and retrograde sepsis McDonald and Heckel [9] now describe a plastic procedure by means of which long continued catheterisation is avoided and the incidence of stricture reduced Briefly the operation consists in splitting the end of the divided ureter and embedding each half subcutaneously into two infolded skin flaps cut from the margins of the main incision Subsequent retraction of the skin flaps during healing maintains the patency of the ureteral orifice, and indwelling catheters can then be dispensed with Satisfactory results are claimed in 13 cases out of 22 operated on during the past eighteen years Although this technique does not entirely eliminate the risks and inconveniences of cutaneous ureterostomy, because of its simplicity it has much to recommend it

CONTROLLED TRIALS NEEDED

SOME of us are concerned because the rate of the increase in true knowledge in medicine seems slow in relation to the immense amount of work done It may be that, as science progresses, more effort must be expended to achieve a commensurate advance But too often results are obtained whose worth is small—though much time, thought, and money has been used up—because they are based on too small a series of observations Thus on many topics a great mass of information has been collected which cannot be integrated because the conditions under which it was collected varied so much When a subject is being tackled for the first time, many small-scale experiments are needed to get a general idea of what is involved, but once this stage is over, large controlled experiments are often needed to test the hypotheses that have arisen We have called for a certain return to planning in our professional affairs,[1] and more planning in experimental clinical medicine would be welcome

An example is the treatment of high blood-pressure Professor Pickering [2] lately contrasted our ignorance (after twenty years' experience) of how useful is sympathectomy for hypertension, with our sure knowledge of the place of drugs in tuberculosis—for there have been few controlled trials of sympathectomy We do not certainly know whether surgery benefits hypertensives (except in very severe cases), much less which operation is most beneficial With the hypotensive drugs, which have been the subject of so much investigation, the position is likely to be little better until a big trial is made with all the major variables controlled No one group of physicians could expect to see enough cases to conduct such a trial but if a large number of workers could be persuaded to treat patients in a controlled fashion as part of a prearranged plan, we might gain reliable evidence as to which drugs are indicated for which patients, and when other treatments (e g, dietary or surgical) are needed That such cooperative schemes can be successful is obvious from many reports of the Medical Research Council, and from such joint efforts as Anglo American investigation of the treatment of rheumatic fever [3]

Professor Sanjivi [4] has proposed that patients with hypertension but no symptoms should be treated with drugs in an attempt to keep the blood pressure normal, and has given an account of some of his patients treated (without controls) with reserpine Dr Hambling [5] expressed the misgivings that many doctors will feel, especially in view of the side effects of such drugs, and in our correspondence columns this week Dr Muhammad takes the view that Professor Sanjivi's patients would have done equally well with reassurance and sedation But the simple fact is that we do not know whether or not they would have done as well, and the only way to decide the very important question of whether or not active hypotensive treatment is worth while is to begin a controlled trial, treating some patients with drugs designed to lower the blood-pressure and others with reassurance and mild sedation This would take many years, though preliminary results would be to hand sooner Treating a small number of patients with transient hypertension, without using controls, will tell us little

Many other conditions call for similarly controlled study Since living organisms contain so many variables, biological science is bound to be less exact than physical science But one way in which the investigator of living creatures can approach exactitude is by observing a lot of them This is not to say that large collective studies can wholly replace individual investigations the gifted research-worker will always be needed to point the way, and the worker who studies a few patients in great detail may provide information (e g, on individual variations and on side-effects) which would be missed in a large study designed to answer specific questions

ANOMALOUS PULMONARY VENOUS DRAINAGE

IN early fœtal life the venous drainage of the lungs is through the umbilico-vitelline system which connects with the systemic pre and post cardinal veins The precardinal veins unite to form the right superior vena cava, and the postcardinal veins unite to form the inferior vena cava At the same time the sino atrial region of the primitive heart tube is forming a localised pouch which becomes the left atrium, and from this a channel extends towards the lungs and finally connects with them to become the common pulmonary vein As this is dividing into the four pulmonary veins, the more primitive umbilico vitelline system is absorbed

Total anomalous pulmonary venous drainage in post-natal life results from the retention of the early stage of development with failure of the heart to make connection with the lungs by the common pulmonary vein In the majority of patients the venous drainage from the lungs enters a persistent left superior vena cava by a common channel and thus connects with the right atrium Less commonly the pulmonary veins drain directly into the right atrium or via the coronary sinus, inferior vena cava, portal vein, or a persistent ductus venosus[1] For life to be possible there must obviously be a right-to left shunt, and this is usually through the atrial septum by means of a patent foramen ovale or an atrial septal defect Part of the mixed venous return to the right atrium will then pass into the left atrium, and part will go through the tricuspid valve into the right ventricle The pulmonary and systemic venous returns are not completely mixed in the right atrium, and the pulmonary stream entering through the superior vena cava tends to be directed through the tricuspid valve into the right ventricle, whereas systemic venous blood from the inferior vena cava tends to go through the foramen ovale into the systemic arterial circulation For this reason pulmonary arterial blood may show an oxygen saturation which is as high as or even higher than that in the systemic arterial blood[2]

The incidence of total anomalous pulmonary venous drainage is greater than was previously appreciated, it accounts for about 2% of all congenital heart lesions[3] Survival into adult life has been reported with increasing frequency,[3] [4] but the disorder is of greatest importance in infancy because 80% of those affected die before 1 year of age[5]

In adults the condition clinically resembles simple atrial septal defect, from which it may be indistinguishable except by radiography or cardiac catheterisation and dye dilution studies[3] In infants the condition may be even more difficult to diagnose Mild cyanosis is often present in later life, but it is seldom obvious in the first six months, even though the systemic arterial blood is somewhat unsaturated The heart is usually of normal size at birth, but enlarges rapidly in the first few months of life A systolic murmur is often heard at the left sternal border and is thought to be due to increased blood-flow through the pulmonary artery, occasionally over the base of the heart there is a venous hum, which probably originates from the abnormal pulmonary venous return[6] The second heart sound in the pulmonary area is split, and in about a third of cases is accentuated owing to a loud pulmonary component associated with pulmonary hypertension Radiographically the heart often shows a characteristic "figure of 8" or "cottage loaf" appearance owing to persistence of the left superior vena cava with enlargement of the right atrium and right ventricle, the pulmonary artery is increased in size and activity and the peripheral vascular markings are also increased The electrocardiogram shows evidence of right ventricular and right auricular hypertrophy

The diagnosis is made from the high oxygen saturation in blood from the superior vena cava or high right atrium and from the unusual finding that pulmonary arterial blood is as highly oxygenated as systemic arterial blood

Of 30 cases reported by Gott et al[7] the majority died in the first three months of life and only 3 were living and past infancy Of the 30, several had severe symptoms, and 4 were submitted to operation Most workers believe that, if there is not severe pulmonary hypertension with pronounced reversal of blood flow through the inter atrial communication, surgical correction should be attempted Operation with the aid of an extracorporeal circulation to by pass the pulmonary circulation, or with hypothermia, has sometimes proved successful, even when undertaken in infants The operation consists in anastomosing the common venous channel carrying the pulmonary venous return to the left atrial appendage, the atrial septal defect being left unclosed[8] In three different series 3 out of 4 patients[1] 3 out of 6,[7] and 4 out of 12[3] survived Total anomalous pulmonary venous drainage must therefore take its place beside other congenital malformations of the heart and great vessels carrying a grave prognosis in early life, which may now be amenable to surgical treatment

INTERNATIONAL FEDERATION OF SURGICAL COLLEGES

AT a meeting representative of surgical colleges in many countries, held at the Royal College of Surgeons of England, with Sir Harry Platt, the president, in the chair, it was unanimously agreed to found an international federation, and the inaugural meeting is to be held at Stockholm in July, 1958 The object of the federation will be the maintenance and improvement of the standards of surgery throughout the world The members will not be individual surgeons, but such national surgical institutions as may be elected to membership

The bodies represented at the preliminary meeting were the Royal College of Surgeons of England, American College of Surgeons, Royal College of Surgeons of Edinburgh, Royal College of Surgeons in Ireland, Royal Faculty of Physicians and Surgeons of Glasgow, Royal Australasian College of Surgeons, Royal College of Physicians and Surgeons of Canada, Académie de Chirurgie de Paris, Belgian Surgical Society, Royal College of University Surgeons of Denmark, Dutch Association of Surgeons, Italian Society of Surgery, Norwegian Surgical Society, and Swedish Surgical Association

Before Our Time

HARVEY

THE OCULAR PHILOSOPHER*

Sir Russell Brain
Bt, DM, LLD, DCL, FRCP, FRCOG

Throughout this week we have been celebrating William Harvey, in the way in which, surely, he would most have wished to be commemorated, by describing the results at the present day of his discovery of the circulation of the blood And what we have heard about the new work on the circulation which has been carried out even during the last twenty-five years shows that his achievement was endowed with a generative capacity for creating fresh knowledge which three centuries have not diminished, but enhanced In making the concluding contribution to this congress, I have naturally asked myself how I could hope to say anything new upon a subject which three centuries of panegyric, including three hundred Harveian orations delivered to the Royal College of Physicians, may well have rendered threadbare But a genius presents a fresh challenge to each generation, and it is therefore appropriate that for a few minutes we should look at Harvey's thought in the light of today

* * *

Harvey, though a man of all time was also, inevitably, a man of his own time, and it is one of the values of medical history that it enables us to see the great originators against the background of the ideas which they took for granted, and so to understand better both the greatness and the limitations of their achievements Harvey's ideas were necessarily expressed in the language of his own day, which presents us with a difficulty of interpretation His thought was sometimes so far ahead of his time that the current terminology was inadequate for it Sometimes, therefore, the words he uses mean more than they meant then, and other than they mean now

This point is well illustrated by his change of view between the *De Motu* and the *De Generatione* on the relative importance of the heart and the blood, and his final emphasis upon the blood in the *De Generatione* "I maintain," he says there, "against Aristotle, that the blood is the prime part that is engendered, and the heart the mere organ destined for its circulation It clearly appears that the blood is the generative part, the fountain of life, the first to live, the last to die, and the primary seat of the soul, the element in which, as in a fountain head, the heat first and most abounds and flourishes, from whose influxive heat all the other parts of the body are cherished, and obtain their life" In the penultimate chapter of the *De Generatione* Harvey deals with the innate "heat" Here he is striving to turn the terminology of outworn ideas into scientific concepts The heat, he says, is the spirit or spirits, and both are nothing other than the blood And according to Harvey "the blood is the first produced and the most principal part of the body, endowed with each and all of these virtues, possessed of powers of action beyond all the rest, and therefore in virtue of its pre eminence meriting the title of spirit" He then goes on to reject the suggestion that the blood must contain other spirits of an aerial or ethereal nature, on the ground that being composed of elements it could have no power of action beyond these elements or the bodies compounded of them "Nor can it be admitted that there are any other bodies or qualities of a spiritual or incorporeal nature, or any more divine kinds of heat" Harvey is careful to define the word "spirit" as he uses it It means what Hippocrates called *impetum faciens*, or moving power implying by this "whatever attempts aught by its own proper effort, and causes motion with rapidity and force, or induces action of any kind" Thus "spirit" might be in part translated "function," in part "stimulus" Here, then, if we penetrate beyond Harvey's words to his thought, we find him making, as best he could in the terminology of his day, the revolutionary statement that the blood is of supreme importance because it carries out a whole range of as yet dimly discerned vital functions (spirits) solely by means of its physical constituents (elements)

Similarly it is easy to miss the fact that even when Harvey's thought was apparently dependent upon archaic ideas he often used them in a new and more profound sense A number of writers have pointed out that he was influenced by two ideas which he derived from Aristotle—the special virtue of circular motion and the belief that the living organism, the microcosm, embodies the same principles as the universe, the macrocosm Both of these ideas are illustrated in a famous passage in the *De Motu*

> "We have as much right to call this movement of the blood circular as Aristotle had to say that the air and the rain emulate the circular movement of the heavenly bodies The moist earth, he wrote, is warmed by the sun and gives off vapours which condense as they are carried aloft and in their condensed form fall again as rain and remoisten the earth, so producing successions of fresh life from it In similar fashion the circular movement of the sun, that is to say its approach and recession, give rise to storms and atmospheric phenomena."

The same comparison reappears in the *De Generatione*, when, again with a reference to Aristotle, the rhythm of life from the egg to the fowl and back again to the egg is described as a circuit and compared to the principle active in the universe which is responsible for the rising and setting of the sun

> "And this is the round which makes the race of the common fowl eternal, now pullet, now egg, the series is continued in perpetuity, from frail and perishing individuals an immortal species is engendered" And, in a phrase with which Thomas Browne might have been pleased, "the egg, I say, is a period of this eternity"

* * *

These ideas of Harvey have been used to illustrate the importance of analogy in scientific thought To a superficial view today it may seem that there is no connection between the circular motion of the sun in the heavens, or of moisture in the atmosphere, and that of the blood in the body Harvey, it might be argued, arrived at the right idea by means of a false analogy His contemporaries, whether or not they accepted his discovery, would have found nothing unreasonable in his use of such analogies, it was a method inherent in the contemporary climate of thought And we, looking back on Harvey from the vantage-point of three centuries, may perhaps pause for a moment to wonder what our successors three centuries hence will think of some of the ideas we take for granted, and indeed justify pragmatically by their scientific results

But it would be a mistake to dismiss, as merely an analogy, Harvey's interpretation of the idea that the microcosm mirrors the macrocosm, that the organism is a model of the universe This was a much more profound conception than the similar contemporary hypotheses of alchemy We see this in a striking passage in the *De Generatione*

> ' But nature, the principle of motion and rest in all things in which it inheres, and the vegetative soul, the prime efficient cause of all generation, move by no acquired faculty which

---

* Final paper read at the Harvey Tercentenary Congress on June 7, 1957

> might be designated by the title of skill and foresight, as in our undertakings, but operate in conformity with determinate laws like fate or special commandments—in the same way and manner as light things rise and heavy things descend. The vegetative faculty of parents, to wit, engenders in the same way as the spider weaves her web, as birds build nests, incubate their eggs, and cherish their young, or as bees and ants construct dwellings, and lay up stores for their wants, all of which is done naturally and from a connate genius or disposition, by no means from forecast, instruction, or reason."

Here we see the full range of Harvey's mind as a scientific philosopher. Beginning with "nature, the principle of motion and rest in all things" he links together gravitation, the fertilisation and development of the ovum, and the instinctive behaviour of insects and birds, as operations "in conformity with determinate laws like fate". Hence the organism mirrors the universe, not in virtue of some occult principle of similarity, but because the universe and its minutest parts are subject to identical laws.

When Harvey seeks to explain how these laws apply to the development of the individual from the fertilised ovum his explanation has been described as vitalistic. What puzzled him was how so complex a structure as the fully developed chick could construct itself out of the homogeneous material which composed the original egg. When Harvey contrasts metamorphosis and epigenesis as modes of development of the organism we see his scientific philosophy at its best. With no knowledge of chromosomes or genes, of chemical organisers or gradients, with nothing on which to build but the unaided observations of his own eyes, he could do no more than reach a statement of the problem, but the strength of his position lies in the fact that he rejected explanatory hypotheses for which there was no evidence. His description of the development of the chick, therefore, is one which, however inadequate it was bound to be, needs only to be filled in with subsequent scientific discoveries, as the following passage shows.

> "Now it appears clear from my history, that the generation of the chick from the egg is the result of epigenesis, rather than of metamorphosis, and that all its parts are not fashioned simultaneously, but emerge in their due succession and order, it appears, too, that its form proceeds simultaneously with its growth, and its growth with its form, also that the generation of some parts supervenes on others previously existing, from which they become distinct, lastly, that its origin, growth, and consummation are brought about by the method of nutrition, and that at length the foetus is thus produced. For the formative faculty of the chick rather acquires and prepares its own material for itself than only finds it when prepared, and the chick seems to be formed and to receive its growth from no other than itself."

Thus, having reached the limit of the knowledge which was possible to a combination of naked eye observation and reflection, Harvey had to explain what he could not understand in terms of what he called "the soul or a faculty of the soul".

It may be said that if this is vitalism, vitalism is merely another name for our ignorance, and some no doubt would maintain that that is all it ever is. But in a broader philosophical sense Harvey was a vitalist, or at any rate, an antimaterialist.

> "They who assign a material cause, and deduce the causes of things either from the elements concurring spontaneously or accidentally, or from atoms variously arranged do not attain to that which is first in the operations of nature. They do not recognise that efficient cause and divinity of nature which works at all times with consummate art, and providence, and wisdom, and ever for a certain purpose and to some good end."

I wonder what Harvey would have said if he could have been shown all that the scientist of today knows of embryology. Growth, form, and nutrition were the key words to him and they are the key-words still. How delighted he would have been at the vast array of knowledge which has come to fill those empty spaces he had no means of filling! And yet I wonder if his restless mind would have been satisfied. Would he have looked beyond the mere descriptions of events to a still elusive *anima*, a principle of form, which we still lack, perhaps because it belongs to a *scientific category yet to be discovered*?

* * *

We speak of Harvey, the observer and thinker, but there are many types of observer and many kinds of thinker. The key to Harvey's thought is surely provided by Aubrey's famous statement that he "did delight to be in the darke, and told me he could then best contemplate". Harvey was a contemplative, and a visionary, whose delight came from reflecting upon the world of Nature, and whose vision found its inexhaustible satisfaction in living things. In Thomas Browne's magnificently apt description he was "that ocular Philosopher and singular discloser of truth". It will not perhaps derogate from Harvey's uniqueness to compare him with another unique "ocular Philosopher," Sherrington, the centenary of whose birth we commemorate this year. Is it altogether inappropriate to compare *The Integrative Action* with the *De Motu*? And though Sherrington's later work *Man on his Nature*, was written with a different intention from Harvey's *De Generatione*, the same spirit shines through both—an almost mystical delight in life seen with the eye of scientific understanding. Sherrington was a poet. Harvey, as far as I know, wrote no poetry, but who that has read *De Generatione* can doubt that he had a poet's delight in words. All this is to be found in that statement of faith which is so characteristic of him, a cry from a heart, indifferent perhaps to the precise formulas of reason in such high matters, but uttering its reasons which the reason cannot know.

> "Wherefore, according to my opinion, he takes the right and pious view of the matter who derives all generation from the same eternal and omnipotent Will, on whose nod the universe itself depends. Nor do I think that we are greatly to dispute about the name by which this first agent is to be called or worshipped, whether it be God, Nature, or the Soul of the Universe,—whatever the name employed,—all still intend by it that which is the beginning and the end of all things, which exists from eternity and is almighty, which is author and creator, and, by means of changing generations, the preserver and perpetuator of the fleeting things of mortal life, which is omnipresent, not less in the single and several operations of natural things, than in the infinite universe, which, by his will or providence, his art and mind divine, engenders all things."

"Finally, I wonder if we in the public dental service are not as much to blame as any one for the present lowly position of children's dentistry in the eyes of the public. Is it possible that if we had said regular six monthly examination and advice only for such a number of children as we dental officers can treat properly in the course of a twelvemonth, we should have been able to produce at least a proportion of dentally fit school leavers? Is it possible that the butter has been spread so very, very thinly that dentally speaking we have failed in our task? Is it possible that the greatest good for the greatest number resulted in dental evil for the bulk of children? The real test of the success of a dental health service lies not in a statistical appreciation in terms of millions of conservations. Intelligent treatment planning based on a policy of a reasonable number of children per operator and on a proper understanding of the growth of the jaws and teeth supporting structures, in the light of end results, designed, not necessarily for perfection but in the light of reason, would in the long run produce a high proportion of healthy, functional mouths."—W. G. SENIOR, F.D.S. R.C.S., *Publ. Hlth*, June, 1957, p. 92.

Conferences

HARVEY TERCENTENARY

DELEGATES from both hemispheres met in London last week for a congress to mark the end of the third century since William Harvey's death. It had been organised by the Harveian Society of London and a committee representing the Royal Society, the Royal College of Physicians, the Medical Research Council, and other bodies concerned with the study of the circulation. Opening the scientific programme at the Royal College of Surgeons on June 3, Mr A. DICKSON WRIGHT, the president read a message of greeting from the Queen.

Growth of Knowledge

The PRESIDENT, introducing the first session, in which the beginnings of medical science were traced from Tudor times, said that three hundred years before, almost to the hour, the clouds had descended over the conscious life of William Harvey as on that summer day the circulation of blood faltered within the brain of its discoverer, and he passed from coma into death. The President recalled the last years of Cromwell's rule, when Harvey, still a Royalist and friend of Charles II, no doubt hoped for the Restoration. Born in the reign of Queen Elizabeth I, he lived for several years in London at the same time as William Shakespeare, who died in 1616—the year in which Harvey as Lumleian lecturer in the Royal College of Physicians first spoke of his work on the circulation.

Prof K. J. FRANKLIN, F.R.S., representing the Royal Society and Harvey's own hospital, St Bartholomew's, and himself the author of the most recent translation of *De Motu Cordis*, spoke of the origins of the great work in the earlier career of its author, and of its still earlier roots in the notable anatomical studies of his teacher Fabricius of Padua, who in his own work *de Venarum Ostiolis* in 1574 had shown that valves are a feature of all the veins of the body. It was probably in the darkened anatomy theatre at Padua, while watching a demonstration in the well-lit arena below, that the purpose of the valves began to suggest itself to Harvey. Fabricius was by then an old man, but he carried on a fine tradition, begun by Vesalius and Fallopius, of study based on factual observation rather than accepted dogma. The Galenic concept of the blood-flow was of some slow, small drift of blood from the right to the left heart, with no inkling of the true circulation or of the speed and volume which it possessed. Robert Boyle had recollected Harvey saying that the valves, everywhere placed so that they can give free passage of the blood to the heart, must imply some other way for the blood to reach the outer limits of the veins and that the arteries must be there for this purpose. It was not known exactly when Harvey returned to England, but it was in the opening years of the 17th century that he became attached to St Bartholomew's, and he lived at Ludgate near old St Paul's. He soon became a fellow of the Royal College of Physicians, then a censor, and in 1615 a Lumleian lecturer—the appointment which led to the release of his researches. Passages from the lecture of 1616 showed that the essence of the work was complete though it was not actually published until 1624.

Prof JOHN FULTON (Yale) carried on the story of the circulation to the time, years after Harvey's death, when the hitherto undetected part of the circulation—the capillaries—were studied microscopically by Malpighi, Leeuwenhoek, Hales, and others. They had, as Sherrington once put it, the capacity to put questions to Nature to which she could reply; and Malpighi, studying the lungs of frogs with the aid of a crystal and candle, might have said, with Homer, "I see with mine own eyes a work trusty and great."

Sir CHARLES DODDS, F.R.S., examined the effect of Harvey's discoveries on his fate as a practising physician. Modern scientific medicine began with Harvey, but paradoxically his own system of medicine was little affected. Things were better now, but the possible conflict between scientific idealism and the conditions of practice could still afford a problem.

Dr F. A. WILLIUS (Mayo Clinic) was unable to attend, but his paper, on historical aspects of the knowledge of congenital heart disease, was ably presented by Dr T. COTTON (McGill). Harvey himself wrote that in the embryo, while the lungs were yet at rest, the two ventricles acted as one. There were many early observations on the post-mortem findings in cases of congenital heart-disease. Full understanding of the structural implications of cyanotic heart-disease was not reached until the description by Fallot in 1888 of *la maladie bleue*, but Rokitansky had in 1875 noted that septal defects appeared to be due to failure of rotation of the developing heart.

Rôle of the Heart in the Circulation

At the next session attention swung sharply to the present. Prof G. W. PICKERING, the chairman, quoted delicately from Harvey, first on the clear body of the little shrimp, with its heart-beat visible within, and the watching of a chick embryo, like a small cloud, its heart a mere point of blood, beating and disappearing. Harvey felt that there had to be a circulation of the blood, or the veins would empty and the arteries burst. Furthermore if the volume of the ventricle, in the open and closed state, were considered, at every beat an ounce or two of blood would be passed on; in half an hour 1000 beats or more would carry forward a greater quantity of blood than is found in the whole body.

Dr L. N. KATZ (Chicago) observed that the control of the circulation was adjusted to its low thrust part, and could be considered under two headings: neurohumoral and intrinsic. The intrinsic quantitative factors were the end diastolic pressure and the after-load or work when contraction begins. He and his team had produced a special heart-lung preparation in which the right heart was replaced by a pump and the isolated coronary venous return could therefore be collected. Flow and oxygen consumption across the coronary circulation was measured and related to other variables. Only a rough correlation could be made between oxygen consumption and the aortic pressure, but a steady relation existed between coronary flow and myocardial oxygen consumption. At a fixed work level they could both be made to increase, but when the work load was changed, as in stress adaptation, the oxygen consumption actually lessened in relation to the increased coronary flow: the heart appeared to change gear, and thus to gain a second wind. Under hypoxia conditions the percentage oxygen extraction increased with the oxygen lack: the coronary flow increased. Efficiency was not the only aim of the heart mechanism: protection was no less important.

Prof K. MATTHES (Heidelberg) recalled that in the fœtus and newborn child there was not much structural or physiological difference between the two ventricles, but that soon the heavier and more variable load on the left heart resulted in changes of hypertrophy rather than actual growth in relation to the right. In the adult the left ventricle could be considered almost as a cylinder in shape and action from the disposition of its fibres, while the softer right ventricle conformed more to the spiral shape of the heart itself. Functionally, the left heart showed a greater blood flow per unit mass of muscle, and the coronary blood-flow was also greater, as was the vulnerability to hypoxia; it was less distensible than the right, having a different modulus. The job of the right ventricle was to maintain, as Gowers showed, the very constant volume of filling of the left auricle. In this it was not the servant of the peripheral circulation; it could change its action quite independently of this In general it was affected by rather slow-acting factors—even those of renal function and extracellular-fluid exchanges—but the left ventricle was attuned to more rapid influences, acting in the coronary supply, and was more sensitive because of its fibre structure and load factors Ligation produced a larger zone of infarction in the left coronary supply than the right

Dr S Weidmann (Berne) had been able, with the help of a tiny glass capillary, to insert an electrode into the actual fibres of the turtle heart and thereby to conduct direct electrocardiography in relation to other changes He showed the differing behaviour of the potentials in contracting auricle, bundle, and nodal material, and also measured the outflow of radio-potassium in the sinus venosus it tallied closely with the phases of contraction The polarisation effects of the cycle were thus confirmed in relation to the electrical and mechanical changes, the latter he whimsically described as a "nuisance," for they tended to jerk his electrodes out The effect of calcium, he showed, is an intermediate one, while it magnifies the mechanical change it does nothing to the electrical potentials

Dr Paul Wood showed a colour film mainly concerned with the jugular venous pulse He recalled Mackenzie's observations and the tracings of Sir Thomas Lewis's polygraph The film showed the pattern of the neck vein movement in health and disease, characteristic formations were shown in patients with tricuspid disease, pure pulmonary stenosis, constrictive pericardium, and endocardial fibrosis

Hæmodynamics and the Coronary Circulation

Prof C Heymans (Ghent) outlined the history of our knowledge of the control of blood-pressure and heart-rate by the baroreceptors of the carotid sinus and the aortic arch, from Astley Cooper's first observation of the pressor and accelerator effect of carotid compression to his own work in progress today The mechanism can be reset, he said, to function at other levels of pressure, and he gave new details of the depressor action of noradrenaline applied to the artery wall in the receptor zone

Prof Gustav Nylin (Stockholm), like Harvey, was concerned with the measurement of stroke and minute volume He described his experiences of angiocardiographic assay and of dilution techniques He had tried to find the volume of blood in the chest and its separate organs, but the calculations were difficult and uncertain

The changes in the circulation at birth, said Dr G S Dawes (Oxford), have received little attention in the past three hundred years Indeed Harvey appreciated the main facts Modern work on sheep and goats attached by the cord to the intact placenta had shown the distribution of the blood with regard to oxygen tension although the ventricles worked in parallel there were inequalities, the head getting more oxygen than the lower extremities Just before birth the fœtus was on the verge of oxygen lack The closure of the ductus, he has found, is delayed a week or more this may be an advantage in anoxic conditions occurring then, and indeed he has found that the diameter is a function of the oxygen tension, and so are the murmur and thrill

Coronary Circulation and Control

Dr Claude S Beck (Cleveland) showed how the distribution of the blood in the coronary arteries might be more important than its amount His striking film of the operation which he has developed [1] was an impressive testimony to the care and patience of his work in this field He felt that the small intercoronary anastomoses formed allow enough blood to reach the right place to prevent the trigger effect of acute local ischæmia in producing lethal ventricular arrhythmia

Pulmonary Circulation

Dr Andre Cournand (New York) described methods of measuring the pulmonary circulation It is not yet certain, he said, where the increase arises in pulmonary hypertension, but he inclined to the view that it might be a local effect of the blood itself in the vessels as in hypoxia, he had found that when one lung was supplied with 8% or less oxygen in nitrogen, though there was not as a rule any change in pressure, the blood flow fell on the affected side after 10 minutes Acetylcholine, which normally did not affect the pressure, caused a profound fall under hypoxic conditions, though the systemic blood-pressure was unaffected He had shown that these effects were independent of the sympathetic nervous system

Prof C V Harrison had studied the structural changes accompanying pulmonary hypertension in mitral and congenital heart disease The most constant change was narrowing of the segmental arteries of the lower zone of the lung, usually diffuse and due to muscular hypertrophy, but sometimes localised and of atheromatous appearance

Cardiac Surgery

A session was devoted to the results of cardiac surgery, with Sir Clement Price-Thomas in the chair Several surgeons outlined their present experiences, and at the end another team spoke by wireless from New York. The growing-point in heart surgery at present is clearly operation on the open heart, made possible by hypothermia Most speakers felt that the extracorporeal machines were here to stay As Sir Russell Brock said, in a masterly account of his experience of the correction of pulmonary stenosis, we must consider the opportunity to improve on the simple, indirect, and often incomplete remedies with which such good results have been gained For each of the subtypes he described the method which he had found suitable in the past

Earlier Dr Maurice Campbell had spoken on coarctation of the aorta The danger time was the third decade, after this the case for operation was not quite so strong He showed the impressive grouped blood-pressure figures in the Guy's series, and gave the reassurance that patients maintained the figure obtained at their first outpatient visit after operation for five years and more With regard to pulmonary stenosis he felt there was still a place for the anastomotic operations with their good results and lower mortality

Cerebral Circulation

Dr Seymour S Kety (Bethesda) described work at the National Institutes of Health on the factors thought to affect cerebral circulation It had been found that mostly intrinsic mechanisms of humoral type were involved, carbon-dioxide tension in particular the flow fell with hyperventilation and rose with inhalation of carbon dioxide The blood-pressure determined the rate of flow only when this was quite low, and then it was the limiting factor Sympathetic denervation, sleep, alcohol in normal doses, and even hypertension did not change the normal value, which was about 50 ml per 100 ml brain per minute Arteriosclerotic cerebral disease reduced it particularly in psychotic cases Papaverine, as in the pulmonary circuit, relaxed vasomotor control and gave up to 25% increase

Prof Th Alajouanine (Paris) had studied the normal and morbid appearances of the cerebral vessels by angiography in both the dead and the living He recognised that transient hemi-phenomena resulted from partial occlusion of any of the big cerebral arteries The intracerebral vessels, he showed, have a great deal of collateral overlap

Dr E H Botterell (Toronto) spoke on his experience of surgery in the treatment of cerebral aneurysm He felt that the limitations of neck ligation operations were severe, particularly in the poor-risk patient The present tendency was to use the protection afforded by hypothermia to cover the risks of an intracranial attack He emphasised the danger of unrecognised mechanical complications of the hæmorrhage hydrocephalus, a large lateral clot resembling a middle meningeal compression in its behaviour, arterial spasm, and, of course, recurrent bleeding He showed some impressive cases of arteriovenous malformation and their cure, and of traumatic arteriovenous fistula in which the patient was becoming semisyncopal from the shunting back of his carotid blood As in the limbs proximal ligation in such a case would often make things much worse because the remaining blood beyond the fistula rushed back into the vein Distal ligation or clipping must therefore be added

[1] See *Lancet*, May 18, 1957, p 1025

Splanchnic Circulation

Sir JAMES LEARMONTH suggested that the time was ripe for the introduction of a unit of blood-flow and that we should follow the physicists and make it an eponym · he felt that we should think in terms of one or more "Harveys"

Dr SHEILA SHERLOCK showed that however the portal pressure had been measured in the past, there was fair agreement on normal and pathological values She noted that the degree of collateral-vein formation was not necessarily an indication of the severity of the portal hypertension—for example, in some very acute cases there had not been time for them to form and in others the very profusion of them might be the means of keeping the pressure down Indeed the spleen might shrink again and even the patent portal vein might not show on a further phlebogram There could be a reversal of the flow

Prof R. MILNES WALKER (Bristol) spoke mainly on the pathology of portal hypertension In the healthy if the portal vein was compressed the pressure beyond rose from 10 to 40 mm Hg This was the level encountered in patients who bled but as Dr Sherlock had said, some with very large veins might not have so high a pressure This did not prevent them from bleeding however Also, children with extrahepatic block had a normal liver and no ascites Their liver was fed only by arterial blood and was often very red in consequence Portal blood was therefore not essential to the liver Ascites though not an indication for portacaval shunting, was not a contra-indication, indeed since it was likely to be aggravated by portal hypertension it would sometimes respond favourably to the shunt in cases meriting the operation because of bleeding Like Dr Sherlock he felt that the spleen should shrink, and had not seen much evidence of any continued hypersplenism once a good shunt had been provided Fibrosis of the liver had little to do with the degree of hypertension but the regeneration nodules had been blamed He drew an important distinction between pre sinusoidal obstruction in which the outlook with a shunt was very good and the various other forms in which post sinusoidal lesions were present—for example the Budd Chiari condition and veno-occlusive disease seen in Jamaica, and in centrilobular necrosis after healing In each of these ascites and rapid liver failure tended to develop and the patients were not helped by a shunt Some damage might be secondary to vascular insufficiency and mixed types did occur The fact remained however, that in severe bleeding forms of the disease only a wide direct end to side portacaval anastomosis could stop the decline of the patient.

Peripheral Circulation

Prof HENRY BARCROFT, F R.S , took the delegates on an imaginary tour of the several laboratories where the normal peripheral circulation is being investigated, and modestly gave credit to everyone but himself for the advances he described The release of vasomotor tone on body-heating had now been shown to be wholly cutaneous, the forearm, physiologically "skinned" by adrenaline iontophoresis, showed no response when only the muscle flow was being measured Edholm had recently shown that ring block with local anæsthetic abolished the forearm response to heating, this was strong evidence for the existence of vasodilator fibres, and Greenfield had produced evidence that these were cholinergic

Prof W D M PATON, F.R S discussed the pharmacological action of ganglion-blocking drugs Some practical points emerged concerning the danger of a fall in blood-pressure in preventing the clearance of relaxants and other drugs He felt that autonomic overactivity might be a serious liability in injury or prolonged operation and that blockade by spinal or splanchnic anæsthesia might protect against shock and hæmorrhage

Prof J H DIBLE distinguished clearly between ischæmia of central or large-vessel origin and the much rarer form in which the distal small vessels are thrombosed With regard to Duguid's revival of the Rokitansky theory of atheroma, there was, he felt, evidence that thrombus could change in this way, but that mural abnormalities could develop at the same time.

In discussing treatment, Prof C. G ROB emphasised that arterial disease is always generalised, and that only when the local features predominate to a disabling extent should surgery be undertaken Of several hundred patients with aortic, iliac, or femoral arterial occlusion only a minority were suitable for operation, and this was particularly true of the femoral type The development of gangrene might lead to a decision to operate, and when arterial reconstruction had been done for this reason the majority of patients had done well Professor Rob ended by reviewing 26 cases of occlusion of the internal carotid artery Where the lesion was localised to the first $^1/_2$ inch or so and obstruction was incomplete, reconstruction had always abolished the symptoms

Other Events

Sir RUSSELL BRAIN's concluding address to the congress in London appears on p 1235 of this issue

On Saturday a historical session was held in Folkestone under the chairmanship of Sir GEOFFREY KEYNES

TRICHOMONAS INFECTIONS

AN international symposium on trichomonas infections, organised by the Societe Française de Gynécologie, was held at Rheims on May 28–30

It was concluded that the apparent increase in the incidence of such infections is probably due to increased awareness and improved diagnosis of the condition In infected women the urethra is usually involved, but other extension beyond the vagina is exceptional Acute trichomonas vaginitis may cause dyspareunia which persists as a psychological condition after the infection has been cured In men infection is much commoner than is generally supposed, and it may extend beyond the urethra to the prostate and seminal vesicles.

A commission was appointed to examine the question Is trichomoniasis a venereal disease? The commission reported that this infection should not be designated as a venereal disease, but its transmission is usually coital, and, as far as public health administration is concerned it should be regarded as a venereal disease

Wherever possible, both partners should be treated in order to prevent reinfection

In a session on pathology, it was concluded that there was no evidence of the existence of any sort of cystic or other resistant form of the organism, and it was emphasised that intestinal trichomonads cannot infect the vagina

The final session was devoted to treatment It was agreed that there is still no satisfactory remedy, many agents appear to be promising in vitro, but in practice there remains the problem of bringing the remedy into contact with the parasite A B Kupferberg (U S A) declared that in clinical trials nothing less than complete parasitological cure should be accepted as a criterion of cure Asymptomatic cases should be treated

THE UNIVERSITY OF SHEFFIELD

POSTOPERATIVE wound infection is still a major problem Colebrook (1955) wrote "There is still much more infection transmitted in our operating-theatres and wards than we should accept" Recent reports suggest that sepsis is actually increasing Strahan (1951) reported an incidence of 4 3% following elective operations for hernia Howe (1954) reported that 7 2% of clean surgical cases became infected Blowers et al (1955) noted a gradual increase in postoperative infection in a thoracic unit, which was closed and reorganised after the infection-rate had risen to 10 9%

After certain changes in the ward and operating-theatre for gynæcological patients at the City General Hospital, Sheffield, the postoperative infection of wounds appeared to be reduced This improvement, however, was not maintained, and a more detailed investigation of the infection-rates before and after these changes was made. The results are reported here

Before July, 1952, two gynæcological units (unit A and unit B) were housed in a single ward, where there were often as many as 42 beds occupied at one time, and all the operations were performed in the general operating-theatres of the hospital, which were often in use continuously day and night After July, 1952, unit A moved into a newly equipped 18 bed ward, and unit B remained where it was, its beds, however, being reduced to 24 Two labour wards, which had been converted into a small gynæcological operating-theatre, were opened for the use of both Units

TABLE I—ADMISSIONS AND ABORTIONS

Period	Unit	No of beds	No of admissions	No of abortions
I	A and B	42	1317	507
II	A	18	580	224
	B	24	771	345
III	A	18	554	205
	B	24	709	330

TABLE II—DISTRIBUTION OF 651 CASES ACCORDING TO PERIOD AND TYPE OF OPERATION

Period	Group 1 (total hysterectomy)	Group 2 (abdominal operations)	Group 3 (pelvic floor repair, &c)	Group 4 (vaginal operations)	Total
I	63	54	53	23	193
II	75	47	73	43	238
III	68	57	68	27	220
Total	206	158	194	93	651

Material

Three one year periods were chosen for study The first period was the year before the above mentioned changes (from July 1, 1951, to June 30, 1952), the second (from July 1, 1952, to June 30, 1953) and the third (from July 1, 1953, to June 30, 1954) covered the two years after the changes

The total gynæcological admissions in the periods under review are given in table I, which shows little difference between the two units as regards the total admissions and the number of abortions

651 cases are reviewed, comprising 193 in period I, 238 in period II, and 220 in period III

Only major gynæcological procedures were studied, as being more likely to provide useful data than the minor procedures and abortions The 651 cases were grouped according to the type of operation (table II) as follows (1) abdominal total hysterectomy, (2) gynæcological abdominal operations other than total hysterectomy, (3) pelvic-floor repair and other vaginal operations in which the peritoneal cavity was not opened, and (4) vaginal operations in which the peritoneal cavity was opened—e g, vaginal hysterectomy, and prolapse *with* pouch-of-Douglas hernia

All cases showing evidence of preoperative infection were excluded from the study The age distribution of the patients operated on in each unit was similar in all the groups We recognise that comparisons between the results in the two units and even between the three different periods need to be made with caution because of sources of bias, known and unknown For instance, the two wards were not at all alike in design, in one unit for some time the skin temperature was recorded instead of the oral temperature, the proportion of very serious cases dealt with varied with the units and with the periods, the standard of the case documentation varied, and the quality of nursing was not uniform throughout

TABLE III—INCIDENCE OF INFECTION (ALL OPERATIONS)

Period	No of patients	No of infections	
		All cases	With chest and urinary infections excluded
I	193	81 (42%)	51 (26%)
II	238	116 (48%)	57 (24%)
III	220	115 (52%)	76 (35%)
Total	651	312 (48%)	184 (28%)

Criteria of Postoperative Infection

A case was considered to be infected after operation if it showed any one of the following pyrexia (100 4°F or more at any time or 99°F on three or more postoperative days), chemotherapy for an infective condition, wound sepsis, secondary hæmorrhage, paralytic ileus, thrombophlebitis

Cases were counted only once, even if several criteria of infection were present simultaneously In the preparation of tables III, IV, and V a case with a chest or urinary infection was not omitted unless this was the only infection present

Results

All Patients

When all the patients were considered together, the infection-rate was found to have risen in period II and again in period III (table III) The overall incidence of infection at 48% was high, but it fell to 28% when urinary infections (which were very numerous) and chest infections (which were very few) were excluded

Table III also shows that, after excluding urinary and chest infections, there appears to be a reduction in the incidence of infection in period II. The reason for this is not clear (see below)

By Units

The incidence of infection in the two units was studied separately (table IV) When all infections are considered, it is seen that the high incidence of infection and the deterioration with succeeding periods were common to both units The results in unit B were affected much more than those in unit A by the exclusion of chest and urinary infections Patients in unit B ran a particular risk of urinary infection (see below)

TABLE IV—INCIDENCE OF INFECTION (ALL OPERATIONS) BY UNITS

Period	Unit A			Unit B		
	No of patients	No of infections		No of patients	No of infections	
		All cases	With chest and urinary infections excluded		All cases	With chest and urinary infections excluded
I	85	33 (39%)	24 (28%)	108	48 (44%)	27 (25%)
II	126	57 (45%)	43 (34%)	112	59 (53%)	14 (13%)
III	124	63 (51%)	53 (43%)	96	52 (54%)	23 (24%)
Total	335	153 (46%)	121 (36%)	316	159 (50%)	64 (20%)

Abdominal operations (groups 1 and 2)—The incidence of infection in each unit was determined for abdominal operations only (table V) This revealed that unit B experienced a significant reduction in the amount of postoperative sepsis in period II, and that the amount of infection was less than in unit A in periods II and III

Vaginal operations (groups 3 and 4)—The incidence of infection in each unit after all vaginal operations was determined (table VI) This revealed that the postoperative infection-rate in unit B was almost twice that of unit A, but this was almost wholly accounted for by urinary infections, and, when these were excluded, unit B appeared to fare very much better than unit A

Frank sepsis—Lastly, it was decided to get some idea of how much of the sepsis recorded amounted to frank abdominal or vaginal suppuration The data for all infected abdominal cases for unit A were therefore re examined (table VII), from which it seemed that just over a quarter of these infected cases showed frank suppuration A few of these patients had serious infections and were very ill

TABLE V—INCIDENCE OF INFECTION (ALL ABDOMINAL OPERATIONS) BY UNITS

Period	Unit A			Unit B		
	No of patients	No of infections		No of patients	No of infections	
		All cases	With chest and urinary infections excluded		All cases	With chest and urinary infections excluded
I	44	18 (41%)	13 (30%)	73	26 (36%)	23 (32%)
II	56	22 (39%)	16 (29%)	66	16 (24%)	12 (18%)
III	62	33 (53%)	28 (45%)	63	24 (38%)	19 (30%)
Total	162	73 (45%)	57 (35%)	202	66 (33%)	54 (27%)

TABLE VI—INCIDENCE OF INFECTION (ALL VAGINAL OPERATIONS) BY UNITS

Period	Unit A			Unit B		
	No of patients	No of infections		No of patients	No of infections	
		All cases	With chest and urinary infections excluded		All cases	With chest and urinary infections excluded
I	41	15 (37%)	11 (27%)	35	22 (63%)	4 (11%)
II	70	35 (50%)	27 (39%)	46	43 (93%)	2 (4%)
III	62	30 (48%)	27 (44%)	33	28 (85%)	4 (12%)
Total	173	80 (46%)	63 (36%)	114	93 (82%)	10 (9%)

Discussion

The results were surprising in two respects Firstly, a postoperative sepsis-rate of 48% (table III) was much higher than was expected. Even when chest and urinary infections were excluded, the incidence was 28% (table III) The incidence of suppuration (unit A) was 12%

Secondly, the less crowded conditions in the wards and the provision of a separate operating-theatre for gynæcological cases were expected to decrease the incidence of postoperative infection but did not do so Although the sepsis-rate after abdominal operations in unit B fell significantly in period II (table V), it was difficult to believe that this was due to the new arrangements, especially when the incidence of infection after vaginal operations in the same unit in the same period was extremely high—93%.

This suggested a fundamental difference in the management of the abdominal and vaginal cases in unit B, and such proved to be the case after vaginal operations an indwelling catheter was left in situ for the first four days and subsequently the patient was catheterised thrice daily until the residual urine was less than 1 oz This may well have largely caused the high incidence of urinary infections despite prophylactic chemotherapy in 25% of these cases The effect was that nearly every vaginal case in this group ultimately received chemotherapy, and this, so far as we can say, was responsible for the decrease in vaginal infection in the old ward - thus the total sepsis-rate, which was 82%, falls to 9% when urinary infections and 1 chest infection are excluded (table VI) This reduction in potential sources of infection could explain the better results obtained with abdominal cases in unit B in periods II and III (table V) when compared with unit A

TABLE VII—INCIDENCE OF FRANK SEPSIS (ABDOMINAL OPERATIONS) IN UNIT A

—	No of patients	No of infections
All infections	162	73 (45%)
Frank suppuration	162	20 (12%)

Because of differences in management of cases in the two units, the apparent difference between them shown in the tables cannot be taken as certainly due to the new arrangements after July, 1952, but suggests that the facilities may have conferred some temporary benefit in period II This suggestion is reinforced by the fact that in the infected abdominal cases in unit A only minor sepsis was observed, during the six months immediately following the new arrangement (first half of period II) All the major sepsis developed in the second six months of period II Unit B, on the other hand had almost an equal number of major and minor infections in both halves of period II.

The average incidence of postoperative infection was very high throughout the survey. What were regarded as substantial improvements in the ward and theatre facilities for the gynæcological patients did little to alter the amount of infection. Several factors may have been responsible. The most important may be that the clean and the septic cases were operated on in the same small theatre, and, through lack of isolation cubicles, were nursed by the same nurses in the wards; and all the surgical wounds were dressed in the open ward, with the inevitable result that cross infection took place. Moreover, there was still a rapid turnover in the wards, with little chance of resting the beds and the wards; and the staff were often shorthanded and overworked. Conditions in the wards, though much improved after the changes in July, 1952, were still not ideal for maintaining a high standard of nursing. Again, any improvement in the incidence of postoperative infection that resulted in the wards may have been offset by the small size and the construction of the new operating-theatre. This was very small, with a high risk of contact infection; there was no special ventilation or air conditioning; sterilising and sluicing were carried out in a small adjacent room through which the staff had to pass after scrubbing up; and the patients were wheeled into the theatre almost directly from the corridor.

Since the results have shown that the provision of a new ward and an additional operating-theatre did not reduce the incidence of postoperative infection, the question arises: how can this incidence be lowered?

As regards the wards, it is clear that much of the old open-ward system is inefficient: more cubicle-type wards are required, and better isolation facilities are needed for the care of infected cases. (It is in obstetric practice, with its special risk of fœtal and maternal morbidity and mortality from sepsis, that such fundamental knowledge has often been used to good purpose.)

The provision of cleaner air in the wards is obviously desirable. Bourdillon et al. (1948) has suggested a built-in suction system which may with justification be included in the hospitals of the future.

Wright et al. (1944) have shown that the sterilisation and oiling of blankets, screens, and floors in surgical wards can cut down the air content of bacteria-contaminated dust. Such a system is not always followed by a reduction in the incidence of infection (Clarke et al. 1954), because different organisms adopt other ways of dissemination.

Another approach to the same problem reverts to the principle of the old carbolic acid spray—i.e., chemical air-hygiene, which apparently can be safely achieved with various aerosols (MacKay 1952). Bourdillon and Colebrook (1946) showed that, every time wound dressings are disturbed, thousands of particles carrying pathogenic bacteria are released into the air, and these workers recommended the setting aside of a surgical dressing room, which, ideally, would be air conditioned.

Operating theatres should be spacious, well planned and should include satisfactory ventilation.

Positive pressure ventilation with filtered air has been shown to be very valuable in preventing infection by airborne organisms (Colebrook 1955).

Such ventilation, modified to produce a down draught of filtered air over the table to avoid still air zones where dust particles could settle over the wound, was considered by Shooter et al. (1956) as beneficial in preventing possible postoperative infection.

Electrostatic air cleaning (Lidwell 1951) is said to reduce bacterial penetration easily to less than 1%.

Bourdillon and Colebrook (1946) showed that the movements of gowned theatre staff increased the number of airborne organisms, and Blowers et al. (1955) found the bacterial content of the air in the theatre greatest during the disturbance caused by the arrival and departure of patients to and from the operating table, the air taking some time to settle after these movements.

Twin theatres would be a big advantage, because the operator alternates between them, thus allowing time for thorough cleaning of the resting theatre and for the air to settle between cases.

Whatever efforts are made to avoid infection from airborne organisms it is essential that the accepted theatre ritual is always closely observed. The origin of the infection and the bacteriology of the organisms involved are often obscure, as is the subsequent spread. In many hospitals planned and built years ago far more work is being done than they were intended for, and such conditions are ideal for the spread of infection. Again "carriers" of infection among the many persons employed in hospitals are an ever-present focus of infection.

Sterilisation must be efficient, and much evidence is accumulating to show that often it is not.

Bowie (1955), from a survey of sterilising apparatus in British hospitals, considered about 90% to be obsolete, and found numerous faults in design and installation—e.g., unsatisfactory mechanisms for the discharge of air and condensate from the steriliser chambers, the superheating of steam in the sterilisers, leading to ineffective sterilisation and damage to heat-sensitive articles, the absence of any means of recording the air condensate temperature, and the connection of steriliser chambers with the underground drains and with the main hospital water supply.

Recontamination of the contents of the sterilisers during drying is considered by Howie and Timbury (1956) to be a possibility where air filters are absent or improperly constructed.

The containers (usually metal drums) in which the articles are sterilised should be of the correct design and not packed too tightly, to allow proper steam penetration. In a busy hospital with an overworked steriliser the strong temptation to overfill drums has to be resisted. Howie and Timbury (1956) point out the importance of liaison between hospital engineer, theatre sister, steriliser attendant, surgeon, and bacteriologist in order to have a complete understanding of the particular sterilising apparatus and thus the maintenance of an efficient unit for sterilisation. Readers are also referred to the authoritative monograph by Perkins (1956), who goes into great detail and gives a most helpful account of the *Principles and Methods of Sterilisation*.

Hospital discipline must be high if minor sepsis is not to reach serious proportions. There may be a high incidence of infection in the hospital unnoticed or perhaps "accepted" until a unit suddenly becomes involved in a serious outbreak. A continual watch on the amount of sepsis not only in each unit but over all the hospital would be ideal: this may be done in various ways—e.g., a "wound book" (Shooter et al. 1956) in which all details of every infected surgical case are recorded and examined.

Colebrook (1955) recommended the establishment of full-time infection-control officers, and even a systematic check year by year on infection in hospital. By such means early action can be taken when infection becomes significant. The closure of wards and theatres at the beginning of each spate of sepsis should improve matters; but often, unfortunately, this cannot be achieved without increasing the pressure of work on the other wards and theatres still functioning. Clearly methods must be sought whereby wards and theatres can be rested periodically for thorough cleansing so that a harmful concentration of bacteria cannot be built up.

The efficacy of chemotherapy and antibiotics is almost a drawback in the prevention of cross infection, for they take away a stimulus and, as a result, "many hospitals have not yet applied all the methods of reducing cross infection which were shown to be of value in earlier studies" (Clarke et al. 1952). These methods cannot be ignored if the control of postoperative infection is to be satisfactory, and they are probably of as much value as ever in dealing with resistant bacteria To prevent the growth of resistant strains, widespread use of prophylactic drugs should be avoided

Many of these measures to reduce postoperative infection are urgently required, for it is only by technical and structural improvements, great care on the part of each individual concerned in the treatment of the patient, and a continual watch for infection that sepsis in surgical wards can be reduced to its proper minimum

Summary and Conclusions

An investigation was made into the incidence of postoperative infection following 651 major gynæcological operations before and after improved theatre and ward facilities had been provided for two gynæcological units in a busy general hospital

The total infection-rate was 48% The criteria of postoperative infection were rigorous, but about a quarter of the total infection included either abdominal or vaginal suppuration

The provision of a new ward and an additional operating-theatre converted from two labour wards did not improve the sepsis rate, which even rose in the latter part of the survey

Some of the means by which postoperative infection may be reduced are discussed

We wish to thank Dr W J Clancy, of the City General Hospital, Sheffield, for permission to study cases under his care

CENTRAL HEALTH SERVICES COUNCIL

THE Minister of Health has appointed or reappointed the following doctors to the council and standing advisory committees for the period ending March 31, 1960

Central Health Services Council

Prof R V Bradlaw, Prof Digby Chamberlain, * T M Cuthbert, O M Duthie, * Prof Robert Platt, P R C P, F M Rose, J G Scadding

Standing Advisory Committees

Medical —Professor Chamberlain, O M Duthie, * Sir Arthur Gemmell, * Professor Platt, F M. Rose, J G Scadding, G W H Townsend

Dental —Professor Bradlaw, A M. Horsnell, J A Moody, T G Ward

Ophthalmic —J H Doggart, O M Duthie, * A B Nutt

Nursing —A Elliott

Maternity and Midwifery —Arnold Walker

Mental Health —John Bowlby, * T E Pilkington

Tuberculosis —Frank Ridehalgh, J G Scadding, G W H Townsend

Cancer and Radiotherapy—Sir Harold Boldero Cuthbert Dukes, Prof R Milnes Walker, J A Stallworthy, Sir Clement Price Thomas, C J L Thurgar, Prof B W Windeyer

* New appointment

INCREASED REMUNERATION OF FAMILY DOCTORS

THE Ministry of Health announces that, after discussions with the medical profession, it has been agreed that the 5% increase in remuneration as from May 1 last shall be distributed among family doctors under the National Health Service as follows

1 The capitation fee will be increased by *6d* to *17s 6d* per annum
2 The loading in respect of the 501st to the 1500th patient on doctors' lists will be increased by *1s 6d* to *11s 6d*
3 Initial practice allowances will be increased by 25%
4 Hardship payments and supplementary annual payments will be increased by 20%

It has also been agreed that the maximum allowance in respect of the salary of a trainee general practitioner will be increased by £75 to £850 a year

The increase in the capitation fees and loadings for the months of May and June will be paid not later than July 31 The other increases will be paid at the end of that quarter (Sept 30) but all will take effect from May 1

Occasional Survey

IRRADIATION OF THE TESTIS

IRRADIATION of the testis is now an established experimental method of investigating the timing of the events within the tubules which add up to spermatogenesis—i e, the development of mature spermatozoa from spermatogonia (stem cells) The assessment can be based either on regular cytological examination of the tubules after irradiation,[1–3] or on genetical analysis of the incidence of dominant lethals in successive matings after irradiation [4–5]

It is well known that the sequence of cell changes in the lining epithelium of the seminiferous tubules which constitutes spermatogenesis passes as a wave of activity along the tubules, thus not only will any one section of the testis at any given time show tubules at different developmental stages, but the phase of the cycle varies along the length of the individual tubule Spermatogenesis is made up of (1) the cycle of the seminiferous epithelium, with the successive cell types spermatogonia A, intermediate spermatogonia, spermatogonia B, and primary spermatocytes, (2) meiosis (reduction division), and (3) spermiogenesis (development of spermatids to mature spermatozoa) Leblond and Clermont[6] describe nineteen stages of spermiogenesis in the rat, based on the structural changes in the acrosome system Using a similar classification, Oakberg[7] gives sixteen stages of spermiogenesis in the mouse, and finds that the seminiferous epithelial cycle extends over the first twelve of these stages, which are used as " markers " to determine the characteristic cell-associations of its different phases

Spermatogonia have a high radiation-sensitivity, which increases through the developmental sequence (intermediate and B types spermatogonia) The division of spermatogonia B to form primary spermatocytes is accompanied by a dramatic shift to the radiation-response characteristic of spermatocytes Following a single dose of 100r to the mouse testis, there is severe depletion of spermatogonia with complete loss of the B type after 5 days, repopulation begins in 10–15 days Loss of spermatogonia is, according to Oakberg,[7] caused by cell death, rather than inhibition of mitosis, though

[7] Oakberg E F *Ibid*, 1956, 99, 391

some of the spermatogonia obviously survive to restart the epithelial cycle. By examining the irradiated testes at intervals up to 38 days and noting the times of disappearance and reappearance in sequence of the different cell types,[8] Oakberg determined the time-limits of the epithelial cycle in the mouse and so the total length of spermatogenesis. According to his reckoning, the seminiferous epithelial cycle takes on average $8^1/_2$ days, and thus the time required for the maturation of one generation of spermatozoa (in the mouse) is 34 days. Earlier estimates of 26 days for spermatogenesis based on the uptake of labelled material,[8 9] are probably due to errors in cell classification and confusion of spermatocytes with spermatogonia, giving an underestimation of 25%.

By ascertaining the relative frequency of a given stage of the cycle in a random sample of mouse tubules, it was possible to assign time-limits to each tubule-stage and thereby to each phase of cell development. On the basis of genetical evidence, Bateman,[10] gives an estimate of 6–7 weeks between spermatocytes and ejaculation of sperm, but following data supplied by Sirlin and Edwards[11] he agrees[5] that this is probably an over-estimate, and represents the total time of spermatogenesis plus an average of 7·5 days for the *transit* of mature sperms from testis to ejaculate.

With the information now available "it should be possible to select tubule stages and post treatment time in such a manner that the radiation sensitivity of any given spermatogenic cell may be determined".[3] Auerbach[12] believes that there is a parallel radiation sensitivity pattern of testis in drosophila and mouse, and thus that we may be dealing with a fundamental property of male germ-cells.

Oakberg[7] reports an incidence of degenerating cells, particularly spermatogonia A, in the normal mouse testis. He regards this as a selection against the more drastic chromosomal aberrations and possibly even genic changes during cell multiplication and growth. Such cell-necrosis is not, however, a normal feature of other actively mitotic epithelium, and it is tempting to relate it to the high radiation sensitivity of these stem cells. As cytological techniques improve, it should become possible to detect with some assurance non-lethal chromosomal damage of cell types, denoting potential mutated sex-cells.

It seems that there must be some local mechanism integrated with the general hormonal control to maintain the timing and spacing of the cycle of cell differentiation in the different tubules, and the recurring cell associations characteristic of each stage of development.

Parliament

The Government and the Piercy Report

In an adjournment debate on June 7 Mr Robert Carr, parliamentary secretary to the Ministry of Labour and National Service, reported progress on the implementation of the Piercy report.[1] Dealing with the group of recommendations on the hospital and medical services he said that all the departments concerned and representatives of the medical profession itself were considering what could be done to give general practitioners and consultants more information about the scope, nature, and potentialities of rehabilitation. The health Ministers were shortly to advise hospital authorities on points raised by the committee's support of planned and purposeful physiotherapy and of the tendency of occupational therapy to offer more realistic occupations and advice and help on how to live with a disability. Each hospital would be asked to consider setting up a rehabilitation committee of its own, and every large hospital would, it was hoped, set up a resettlement clinic to review difficult cases of disablement. These clinics had proved valuable not only in dealing with the problems of individual patients but also as a means of drawing together the different agencies concerned in rehabilitation and resettlement. Hospital boards would also be asked to have regard to the needs of rehabilitation departments in drawing up their capital programmes. But clearly development must be conditioned by the availability of funds and staff. It was essential that we should make the best use of existing resources before seeking to expand them.

Pharmaceutical Services Committee

The Minister of Health has set up a committee with the following terms of reference:

Having regard to the increased cost of prescriptions issued in the National Health Service, to investigate the factors contributing to this cost and to make recommendations.

The members of the committee are:

Sir Henry Hinchliffe (chairman), a member of St Mary's Hospital, Manchester, H.M.C. and director of the Manchester chamber of commerce; Dr William Brockbank, dean of clinical studies and lecturer in medicine, Manchester University; Mr K. E. Capper, PH.D., editor of the *British Pharmaceutical Codex* and joint secretary of the National Formulary Committee; Dr H. C. Faulkner, member of the General Medical Services Committee and assistant M.O.H., London County Council; Dr F. E. Gould, member of the General Medical Services Committee and secretary of the Birmingham local medical committee; Dr D. V. Hubble, physician, Derby Royal Infirmary; Dr C. A. Keele, professor of pharmacology and therapeutics in London University at Middlesex Hospital Medical School; Mr M. G. Kendall, SC.D., professor of statistics, London University; Dr A. M. Maiden, a rural practitioner and member of the General Medical Services Committee; Dr A. D. Stoker, a rural practitioner and member of the General Medical Services Committee; Dr A. P. Thomson, dean of the faculty of medicine and professor of therapeutics, Birmingham University.

One appointment is outstanding. It will be filled by another general practitioner, and it is expected that he will be from Wales.

QUESTION TIME

Influenza Precautions

Sir Frank Medlicott asked the Minister of Health what steps were being taken by his department and by the public health authorities generally to deal with the possibility that the new form of influenza which was now raging in the Far East might spread to Europe and reach Great Britain.—Mr Dennis Vosper replied: The outbreaks of influenza in the East are being caused by a new variant of the virus, but all reports are that the illness is clinically mild in character. There are standing arrangements for information to be supplied about outbreaks of influenza in this country through general practitioners, industrial medical officers and others, and port medical officers report epidemic influenza among persons arriving in this country. As a precaution, practitioners are now being reminded of these arrangements. The characteristics of this new strain of virus are being investigated at the World Influenza Centre and in other research departments.

North Staffordshire Royal Infirmary

Dr Barnett Stross asked the Minister of Health whether he was aware that the closure of the operating theatre in this hospital was causing pressure on the other hospitals in Stoke-on-Trent and that both patients and medical staff were inconvenienced; and when the new theatre would be completed.—Mr Vosper replied: I am aware of the difficulties which have unfortunately resulted from the closure of these theatres. The regional board has arranged for beds to be available in another hospital for certain surgical cases, and for extra operating sessions at two further hospitals. It proposes to provide a temporary operating theatre at the Royal Infirmary as soon as possible, and hopes to be able to provide a new permanent twin theatre suite within two years.

At the end of 1956, in England and Wales 6247 mental defectives were awaiting admission to institutions.

In England Now

A Running Commentary by Peripatetic Correspondents

THE life of a medical registrar in England to judge by the articles now appearing in a Sunday paper, has many drawbacks and is far from exciting How different things can be in tropical Africa Twice the amount of work, constant difficulties such as inadequate drugs and equipment, but always something out of the ordinary just around the corner, or perhaps—more accurately—a little further away

Last week my chief called me in and asked me whether I would care to see a patient for him as he was unable to do so, and would I contact the local G P ? From the G P I learned that the patient lay ailing far across Lake Victoria As money was no particular object, an aeroplane had been chartered to take the " specialist " (me), the G P , and two of the patient's relatives to the bedside There were a few seats vacant, said the G P , and would I care to take my wife along ? My wife had slipped another spool of colour-film into her new camera almost before the telephone was back on its stand

A rainy Sunday morning saw us setting out over the lake, the E C G machine tightly strapped into a seat of the aged de Havilland aircraft Visibility was limited by driving rain and black cloud I began to regret my eagerness to be airborne Suddenly a thin ribbon of blue sky appeared ahead of us and soon we were flying through brilliant sunshine, with small wooded green islands below and in the distance the green shores of Tanganyika Then over small thatched huts, each surrounded by its grove of banana trees, an occasional splash of colour from a woman's dress, and a peculiar three-dimensional effect as we passed over the tall palm-trees My wife's camera clicked furiously, while I wondered whether this was all in keeping with the serious nature of our mission and tried hard to look as if it was all her own idea anyway, and her camera Down to earth, where a large Mercedes-Benz whisked us into the small town nestling among dark green-brown hills which sloped down to the remarkably blue lake It seemed for all the world like a scene from a Western movie, rather ramshackle and a shade dusty, with figures sprawled idly on verandahs in the sunshine

The patient had responded rather well to the local doctor's treatment, and sat perched on his bed eagerly awaiting the visitation While I took his history, a steady flow of friends and neighbours passed through the room; a quiet hum of agitated whispering accompanied our conversation But it all seemed so accepted a procedure that I had not the heart to empty the room By the time it came to examining the patient the audience had grown Small children peered in at the doors and windows, and only by dint of persuasion could I thin the spectators to a respectable number for a rectal examination We soon discovered that the electrical fittings were unsuitable for the E C G machine, and after a hurried consultation the local electrician and his mate appeared Large quantities of wire and equipment strewed the floor and finally we were ready for the actual recording Once again the room was crowded, and it was all I could do to preserve my gravity amid the obviously admiring throng of men, women, and children I can hardly be blamed for using twice the usual amount of paper While I sat looking at the record, the patient's business partner decided that a little of the limelight should fall in his direction and amid sighs and groans prostrated himself gently on a bed in the next room, insisting that he be seen by the specialist as soon as possible I think he had visions of his partner's rapid retirement and wanted to stake his own claim to physical disability before it was too late

All this time my wife had been on a sightseeing tour of the district On her return it was only proper that she should be brought in and introduced to the patient and his friends To the joy of the assembled gathering and to my wife's embarrassment she was solemnly presented with a beautifully embroidered handbag After all this there could be no unceremonious rush to the airfield, but a gentle drive into the hills above the town, through the coffee-plantations and past the beach where a notice warned one to be careful of the hippopotami which came out of the lake in the evenings and wandered through the gardens A quiet lunch at the hotel looking over flaming cannas and gleaming yellow cassia trees to where the waves broke on the sandy bay, and then the time had really come to leave

Flying back I reflected how different this all was from the daily routine I had known in England, and looking down on the sparkling waters, the small canoes paddling between the islands, and the white birds circling slowly below, I gave thanks for the opportunities that still exist to lead a life that is just that little bit different

* * *

My patients used to come into the waiting-room worried, depressed, and sometimes bored, only to find others in the same unhappy state Some picked up the torn and dog-eared magazines on the table to while away the time Others chatted in lugubrious tones with their fellow sufferers All were concerned with their own ailments more than anything else

Since I have hung on the wall an example of abstract art all is changed Two patients look at it and after some strongly worded criticism agree cordially that it is all nonsense But they go on making comments as they continue to look at it, and for the moment at least forget their troubles Another patient looks at the picture and wonders if there could be something in it which is not readily apparent He studies it, compares it with conventional pictures, and forgets the pain in his leg To another patient the painting comes as a refreshing shock Perhaps to another it tells a story Another seeks to justify it, either to himself or to his neighbour, as a work of art

Whatever one may think about it as " art," my picture has banished apathetic gloom from the waiting-room

* * *

The pathologist's report on an unremarkable appendix read (perhaps somewhat less than ceremoniously) " vermiform appendix " The surgeon, who was temperamentally non-vermiform, read the two words and, turning to the small company which had forgathered to savour his counter-attack, declared " What did I tell you ? Worms in the appendix Bad things, worms " His last word may have been his counter-attack

* * *

For the patient life in hospital is curiously unreal Doctors make sporadic appearances The H S acknowledges the fact that you're human and makes encouraging remarks from time to time about getting up The Registrar appears in the middle of evening ablutions and does not stay He promises to return The Consultant, accompanied by the H S looking serious, looks at you briefly and then at your case-notes at the end of the bed and goes away talking about an entirely different patient

You begin to believe that you're not who you thought you were This thought is encouraged by the arrival of two ominous-looking visitors in black, with black ties You can almost feel them measuring you up to see if you will fit into one of their existing coffins or whether they must make another However, they introduce themselves obviously under the impression that they know who you are, but this doesn't help at all One is someone's father, which is fairly reasonable, and you make conventional remarks about how nice to see them and how good of them to come They say that they expect your parents will return to Ashby de-la-Zouch in the morning, you're not quite clear-headed enough to say that perhaps you're not the person they think you are and mutter something about your parents not living in Ashby de-la-Zouch They take their leave suddenly and you wonder whether, perhaps, you do not come from Ashby de-la-Zouch after all

I m a sittin at ease in me parlour
On Sunday, the second of June,
Takin Elgar s " The Dream of Gerontius "
It's a luverly arternoon,
When they calls me to see Mrs Uxtable
—A thing wot they frequently do—
So I ops to er elp as per usual
—And when I gets ome the Dream's through
Now I ain't one to grouse about hours,
Don't ask to be paid overtime,
But when they cuts into me culcher
I calls it a perishin crime

Letters to the Editor

RADIATION AND INFLUENZA MUTATION

SIR,—The wise suggestion in your annotation of June 8 that we should get ready for a winter epidemic of infection by the new variant of influenza virus A that is now ravaging South-east Asia, prompts some consideration of the possible origin of the variant. Viruses share with more elaborate organisms the ability to mutate under the influence of radiation. Mutations in all organisms are more likely to be detrimental than advantageous, but the probability of advantage becomes greater the simpler the organism. It is among the viruses therefore that increased radiation is most likely to lead to an improvement in performance. One aspect of improved performance is the ability to circumvent the specific immunity of the population that is being attacked and this is what the new variant of influenza seems to be able to do.

Mutations, whether in people or viruses, do not carry labels explaining their origin. What is expected as a result of increased radiation from nuclear bombs or other sources is simply an increased frequency of mutation. East Asia is the area that has already suffered most from "fallout" coming from both Siberian and Pacific tests. There is therefore no intrinsic improbability in the idea that this influenza epidemic is yet another evil consequence of these tests.

HYPERTENSION: PRESYMPTOMATIC DIAGNOSIS AND TREATMENT

SIR,—I was interested to read Professor Sanjivi's letter of Feb. 2 and would like to comment on some controversial points he raised.

He says "we are not unduly nervous about telling a patient that he is suffering from tuberculosis, valvular heart-disease, or diabetes. Why should then we continue to teach that it is best not to tell the hypertensive patient that his blood pressure is raised?" Professor Sanjivi perhaps ignores the fact that we know little about the pathogenesis of hypertension. It may be a psychosomatic disorder, where stress and psychological upsets play a big part. If so, telling the patient that he has "hypertension" will still further trouble his already agitated psyche. By telling his patients that they have hypertension, Professor Sanjivi may have done great harm and made them more conscious of their mercury levels. Patients with slightly raised blood pressure, as in the case he quoted, seldom complain of symptoms apart from those of "anxiety neurosis." These symptoms respond readily to reassurance, regulation of life, avoidance of hurry and worry, and a sedative. To measure a patient's health by his mercury column is to do him the greatest disservice. Professor Sanjivi is happy about his results, but he should realise that the patients he is treating with hypotensive drugs could have equally well responded to reassurance and sedation.

He continues, "The classification of essential hypertension into benign and malignant is completely misleading. It should be given up." I think this is going too far. Malignant hypertension has a poor prognosis and requires aggressive treatment by ganglion-blocking agents or by sympathectomy. If Professor Sanjivi does not like the word "benign," he may call it "non-malignant" hypertension. I think the classification of hypertension into benign, accelerated, and malignant forms might satisfy him.

I think that the benign and malignant types are in fact two different diseases having in common only the raised blood pressure. The characteristic lesions of benign hypertension are hyaline degeneration of intima of small arteries and medial hypertrophy of muscular arteries. The essential lesion of malignant hypertension is fibrinoid necrosis of arterioles. Clinically the brunt of benign hypertension is borne by the coronary and cerebral arteries, the patient usually dying of congestive heart failure, coronary thrombosis, or cerebral thrombosis. Not more than 10% of patients die from renal failure. But in malignant hypertension, the disease runs a very acute course, most patients dying of renal failure. Hypertensive encephalopathy and cerebral hæmorrhage are not uncommon. Cardiac involvement, however, is uncommon, though acute left ventricular failure is sometimes seen. The patients with benign (non-malignant) hypertension may live about a normal span, but without treatment patients with malignant hypertension seldom survive more than eighteen months. The occasional transition of benign into malignant hypertension may be taken as evidence against this concept. I believe that, pathologically and clinically, benign and malignant types of hypertension are so different that it is not very logical to regard them as different varieties of one disease of unknown ætiology. If the course of benign and malignant hypertension is analysed in many cases, the two types of hypertension may turn out to be two different diseases, as in nephritis types I and II. Occasionally type I nephritis may become "nephrotic," and the clinical picture resembles type II nephritis; perhaps, in the same way, benign hypertension occasionally becomes malignant.

Professor Sanjivi writes: "Of the many fallacies surrounding essential hypertension, perhaps the most serious is that there is no hypertension in the rice-eating people of the East." I believe he underestimates the significance of the rice diet. Its hypotensive qualities are essentially due to its low salt content. Hypertension may be common in Madras where people take too much salt and spices, but its incidence is certainly very low among rice-eating people in the East—e.g., in the Hyderabad division of West Pakistan, where salt intake is not so great. Indeed, the lower incidence of hypertension in the tropics (mostly backward countries of the world) may partly be explained by excessive loss of salt in sweating, especially during the summer, which lasts for about eight months a year in Pakistan and India. In most patients from the countryside with hypertension the disease is secondary to pyelonephritis, renal calculi, or other disorders. In my experience in Pakistan, the prevalence of essential hypertension is directly proportional to the stresses to which a person is exposed, and the incidence is enormously high in educated people holding executive or professional jobs; and the disease is more prevalent in big cities than in villages.

STEATORRHŒA AND HYPERPARATHYROIDISM

SIR,—I have read with interest Professor Dent's letter (June 8) in which he expresses surprise at the simultaneous occurrence of the biochemical features of hypoparathyroidism and the radiological features of hyperparathyroidism. He proposes to call this condition "hypo-hyperparathyroidism," and believes that it can be explained only by destroying "one of our present concepts."

In your annotation of May 25, however, you draw attention to the fact that tetany (with the biochemical features of hypoparathyroidism) may occur in rickets and which suggests a possible explanation for this course of events—namely, that parathyroid overactivity, giving rise to rickets, may go on to parathyroid "exhaustion," giving rise to tetany.

This explanation adequately accounts for the contradictory features of Professor Dent's two cases without destroying any of our present concepts and without introducing a self-contradictory neologism.

Gardiner Institute,
Western Infirmary,
Glasgow, W.1. JAMES CROOKS

SIR,—In his letter of May 25 Dr. Jackson suggests that the simultaneous occurrence of steatorrhœa and *idiopathic* hypoparathyroidism, described by several authors and also by Salvesen and Boe,[1] cannot be fortuitous, and he believes, that this combination is a definite "syndrome." He also mentions our analysis of 85 cases of steatorrhœa, in which we concluded that hypoparathyroidism often exists in this condition, because the serum-calcium remains low, instead of being raised by increased activity of the parathyroids, whose function it is to keep the serum-calcium at a normal level. But this is a *secondary* hypoparathyroidism, which we have seen in relation to the effect of undernutrition on the endocrine glands, so apparent in sprue.[2]

The hypocalcæmia in ordinary cases of sprue is primarily caused by vitamin-D insufficiency and by loss of calcium as calcium soaps with the fatty stools. In the "syndrome" cases mentioned by Dr. Jackson the hypocalcæmia is primarily due to an existing *idiopathic* hypoparathyroidism and the development of steatorrhœa with fæcal loss of calcium should tend to aggravate the hypocalcæmia. These two different kinds of hypoparathyroidism in sprue should not be confused.

We have pointed out[1] that bone lesions of osteomalacia seem to be more pronounced in the cases with a normal or nearly normal serum-calcium and a low serum-phosphorus, indicating a high activity of the parathyroids with resultant loss of calcium from the bones. The secondary hypoparathyroidism in other cases in a certain way protects the bones, but exposes the individuals to the dangers of tetany.

H. A. SALVESEN.

FATAL CARDIAC ARREST WITH FLUOTHANE

SIR,—Dr. C. A. Foster has given a timely warning (June 1) that 'Fluothane' (halothane) is an extremely powerful anæsthetic, and if pushed to high concentration will cause a dangerous fall of blood-pressure, and, in an unatropinised patient, rapid cardiac arrest.

Fluothane allows a quiet trouble free induction without laryngeal or bronchial irritation, and stabilisation of anæsthesia is quickly obtained; and, so long as the patient breathes automatically, and there is no excessive fall in blood-pressure, there is no safer non-explosive volatile agent. But it is essential to keep constant record of the blood-pressure, preferably by an oscillometer, as apart from the lengthening of expiration which, with the quiet breathing associated with halothane anæsthesia, may be difficult to detect, the falling blood-pressure is the most important warning of increasing blood concentration.

Owing to the present cost, closed circuit techniques have naturally become popular. Using a Waters' canister, completely closed, a flow of not exceeding 1 litre of oxygen blown over the surface of a fully open Boyle's bottle, containing 40 c.cm. of fluothane, will produce adequate light anæsthesia with practically no fall in blood pressure.

Bronchial relaxation is so complete that respiration is easily controlled. It must be remembered, however, that under such conditions it is only too easy to reduce venous return to the heart by increasing intrapleural pressure and so lower the blood pressure; if at the same time the concentration of fluothane has been in any way increased, cardiac arrest is possible.

This is no condemnation of fluothane, but of the technique. Fluothane is an excellent anæsthetic agent. Its ease of administration is perhaps its greatest danger because with a powerful drug a demand is essential for greater vigilance.

IMMUNOLOGY OF THYROID DISEASE

SIR,—Professor Wyburn (June 1) has drawn attention to the pioneer and apparently forgotten work of Leo Loeb in the field of tissue transplantation and organ specificity.

This prompts me to point out that Loeb[1] also invented tissue culture, ten years before the classical paper of Ross Harrison[2] who is usually credited with the discovery. Furthermore, Loeb and Fleischer[3] were the first to culture adult mammalian organs in vitro. In this work they discovered the importance of using a gas phase of oxygen rather than air, when adult, as distinct from embryonic, tissues were to be cultivated. Even today this latter point is not fully appreciated.

M.R.C. Radiobiological Unit,
Harwell, Berkshire.
O. A. TROWELL.

SIR,—In your leading article of May 25 you suggest that the initial event in Hashimoto's disease is a leakage of thyroglobulin from the acini; and that the complement fixing antibody is specific for extracts of thyrotoxic glands.

If this is true a high incidence of Hashimoto's disease should be found among cases of hypothyroidism following partial thyroidectomy, and the search for antibodies and the histological examination of the thyroid remnants in these cases would be rewarding.

Supporting this idea is the fact that postoperative hypothyroidism is much commoner in Graves's disease, where thyrotoxic tissue must be cut across, than in toxic nodular goitre, where the toxic tissue is usually removed intact.[4] Bartels states also that a high incidence of "strumitis," defined as "excessive lymphocytic infiltration and fibrosis," is found in the resected specimens in cases where hypothyroidism subsequently develops.

Perhaps it is stretching the idea too far to suggest that the rather surprising success of partial thyroidectomy in Graves's disease may be partly due to the "Hashimoto process" initiated by surgery.

Boscombe, Hants.
A. POLLARD.

ANÆSTHESIA FOR CÆSAREAN SECTION

SIR,—I am interested in the anæsthetic implications of the article on elective cæsarean section and neonatal deaths by Dr. Strang and his colleagues (May 11).

While there are no anæsthetic details, the phrases "The times taken to establish normal respiration (mean 5 minutes) are longer than after vaginal delivery. This delay was probably due to the maternal anæsthesia" and "The baby is usually anæsthetised" deserve comment.

In the Blackburn Hospital Group we have for some time used a method of anæsthesia for cæsarean section which does not anæsthetise the infant, and spontaneous normal respirations usually occur within a minute of delivery.

The mother is visited by the anæsthetist on the day before operation for the usual preoperative examination, and a full explanation of preoperative procedure. She is given a barbiturate sedative the night before operation and where the operation is to take place in the afternoon, she might also be given methylpentynol three to four hours before coming to theatre. Atropine gr. $^1/_{100}$ is given 45 minutes before operation, and in theatre all the skin preparation, towelling, &c., is done before the anæsthetic induction. When all is ready 0.3 or 0.4 g. of a $2^1/_2$% solution of thiopentone mixed with 80 mg. of gallamine ('Flaxedil') is injected intravenously, followed by 25–30 mg. of pethidine. A syringe containing 0.5 mg. ergometrine is attached to the same needle, and strapped to the arm so that it can be injected immediately the baby's head is born. The incision is made as soon as the thiopentone gallamine injection is completed. The maternal lungs are inflated with a mixture of 50% nitrous oxide in oxygen. The infant is delivered usually within 3 min. The longest time taken has been $3^3/_4$ min., and the shortest $2^1/_4$ min. from the anæsthetic injection. Most infants are a good pink colour and cry lustily immediately and even before separation from the placenta.

[4] Bartels, E. C. *J. clin. Endocrin.* 1953, 13, 95.

Since we have been using this method, I have not known it to be necessary to use resuscitative measures, apart from dry suction of mucus from the nasopharynx, which is done by the surgeon or his assistant before the baby is handed to the waiting midwife.

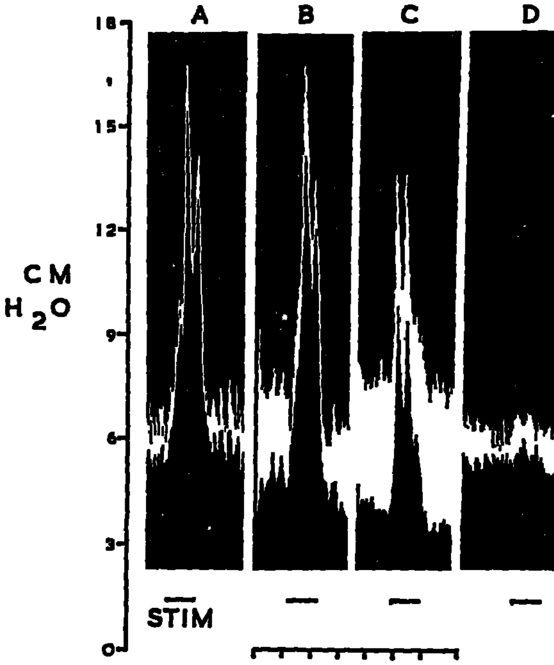
Once delivery is complete, anæsthesia proceeds as for any abdominal operation, an endotracheal tube being passed if necessary. As a rule, the mother is allowed to recover consciousness as soon as the last stitch is inserted, and she knows the sex and weight of her baby before she returns to the ward.

Blackburn MARGARET C. WATKINSON

DUODENAL ULCER

SIR,—As long-term studies of vagotomy and gastroenterostomy come to be published, it seems that this operation may prove to be better than gastrectomy in the treatment of chronic duodenal ulceration. Mr. Hindmarsh (June 1) stresses the importance of complete nerve section, and it would seem that section of all nerve trunks is of crucial importance in the operation. Hitherto no method has been available for testing completeness before the abdomen is closed.

We have developed a simple and safe technique which records quantitatively gastric motor function in response to vagal nerve stimulation. Used initially on animals, it has now been successfully applied to man. The method (later to be published in detail) consists in recording intragastric pressure changes in response to vagal nerve stimulation applied by an electrode around the lower end of the œsophagus. Not only can major trunks be demonstrated in this way, but so too can fine trunks which might have been otherwise overlooked (see figure).



Effects of vagal stimulation on stomach motility. Fluctuations in baseline are due to respiratory movements. At each mark vagus nerves were stimulated for 1 min. with 2 msec. shocks at a rate of 10 per sec.

A, Before nerve section.

B, After cutting the posterior nerve.

C, After cutting a large anterior nerve. A rise in pressure was still obtained, showing that a nerve trunk remained undivided. This was found and cut.

D, The effect is abolished, showing that no trunks remain in continuity.

We would like to thank Professor Sir Lindor Brown for his advice and Dr. E. H. L. Harries for his help in the early stages of this work.

West London Hospital, W.6, and Department of Pharmacology, Royal College of Surgeons of England HAROLD BURGE J. R. VANE

INJURY DUE TO ATOMIC EXPLOSION

SIR,—The reporting of the American Surgical Association's meeting, in *The Lancet* of May 25 (p. 1071), has gone astray in the first two paragraphs.

None of the Marshallese died. The 50% mortality at 200r (which none of them suffered), even if it be only a misprint for 5%, is probably excessive in any circumstances.

In the subsequent paragraph, which deals with facts as to the effects of radiation on dogs, there is included an opinion as to surgery for humans which is, to say the least of it, open to doubt. It is only too easy to extrapolate from limited experimental experience to dicta as to probable happenings in man.

London, W.1 E. ROCK CARLING

THE CHILD'S RIGHT TO ADOPTION

SIR,—Adoption is a controversial subject on which many people express strong views. Some points, however, are so delicate, or are thought to be so much at variance with public opinion, that they are rarely discussed openly. For instance, although there is no legal bar to the adoption of legitimate children, it is in fact difficult to achieve, because most adoption societies and children's officers reflect public opinion and refuse even to consider such a proposal.

The arguments usually put forward against it are that parents must be made to accept their responsibilities, that relieving them of their unwanted children would encourage them *to have more*, and that it would encourage irresponsibility, and be a threat to family life. All these arguments may be valid, but by taking this view society is surely sacrificing the real interests of many children—perhaps in order to gratify its own desire to punish the parents.

Anyone who works with children knows that there is no more pathetic and tragic group than those who are, and always have been, unwanted. Though they may suffer no overt neglect or cruelty, they present problems of disturbed behaviour, delinquency, and psychosomatic illness which are intractable; for if a child is unwanted no amount of outside help can ever make him feel wanted. If we admit that to be unwanted is about the greatest misfortune which can befall a child, are we not under an obligation to avert it whenever possible by making adoption easier?

If such children were accepted for adoption, society would benefit by the decrease in the number of misfits and delinquents; the adopting parents, who now wait years on the lists of adoption societies, would benefit by gaining a child sooner; and the actual parents would benefit by relief from a burden which they resent. Most important of all, the children themselves would have the chance of a happy family life.

As it seems to be so much to everyone's advantage, why is it not allowed? Partly, perhaps, because the public does not understand the extent of the problem, but also because society seems to think that it is a sin for parents not to want or love their children and that somehow they can be made to do so. It would be more realistic to accept the regrettable fact that some parents do not, and never will, love their children. It is fruitless to argue that they should not have them if that is how they feel about it; for despite admonition, censure, and moralising, unwanted legitimate babies will continue to be born

It will inevitably be argued that this change would open the gates to abuse and complications But an abuse does not invalidate a principle, if the principle is generally accepted The rules governing all good adoption procedure would naturally have to be applied, and care taken to weigh carefully the best long-term interests of each baby, its real parents, and its adopting parents It would be naïve to pretend that adoption is always successful, but it seems the best possible means of dealing with this tragic situation

A second point which is seldom discussed, because we have in this country a deep respect for each other's religious beliefs and differences, is the denominational bar There is at present a shortage of Roman Catholic adopting parents and as a result many illegitimate babies of Roman Catholic mothers are denied the chance of adoption and are brought up in baby homes A mother's wishes about the religious upbringing of her child must be respected, but where mothers only claim denominational membership for form-filling purposes and have no real feeling about it, it seems to me wrong to allow this label to prevent babies from being adopted when there are so many parents waiting to give them a home

HOME CONFINEMENTS

SIR,—About this time last year you assisted the London Regional Obstetric Committees by publishing a letter of mine[1] to the effect that, save in exceptional circumstances, practitioners who qualified after Jan 1, 1931, and who wished to be included in the London list of general practitioner obstetricians would, as a condition of admission to that list, be required to have held a resident house-job in obstetrics for a period of six months It was then indicated that any applications received prior to May 1, 1957, would be considered in the light of the conditions which obtained prior to that date

At the instance of the London Obstetric Committees I would again ask for the hospitality of your columns to remind all prospective applicants that the new requirements are now being put into effect

Public Health Department
County Hall
London, S E 1

J A SCOTT
Chairman
London Local Obstetric Committee

CHILDREN IN HOSPITAL

SIR,—As a layman whose occupation includes the reading of medical journals, but also as a parent, I was surprised to find that it was necessary to use six of your columns to demonstrate, in Dr Vaughan's article of June 1, what any intelligent parent could have told your readers—namely, that a simple, reassuring explanation given to children admitted to hospital will almost inevitably satisfy them Indeed, very much could be learned by the staffs of our hospitals if they would consider, more rationally, the need for reassuring even then adult patients It takes very little imagination to realise that people admitted to hospital are almost invariably frightened and disturbed, and that by overcoming this very real upset in their lives as far as possible, much will be done to ease their suffering So much good is done that it makes the notable lapses much more difficult to understand

Surely it can now be accepted that nearly all patients are much happier to know what is going to happen to them and to be relieved of the many and largely unfounded fears with which, quite understandably, they torment themselves

One simple solution, already used, I believe, by the more enlightened, is to have printed cards telling patients or relatives as much as they need know to give them some degree of reassurance It would be a rather grave indictment of those responsible if it should prove necessary to have hospital staff whose sole duty was to reassure patients and make their hospital experience less frightening

MEDICAL ABSTRACTOR

SEASONAL INCIDENCE OF MEGALOBLASTIC ANÆMIA OF PREGNANCY AND THE PUERPERIUM

SIR,—The results in Dr Thompson's interesting article of June 8 might not represent the true seasonal incidence of the disease unless all the cases which occurred during the period under review, were diagnosed Dr Thompson has reviewed a series of 105 patients, collected from three hospitals during a period of twenty-three years, but it seems probable that the total number of cases occurring during this period would be considerably higher than this

During 1956, 30 cases of megaloblastic anæmia of pregnancy and the puerperium were diagnosed at Whiston Hospital, Lancashire, and it is unlikely that there were any other cases, in which the diagnosis was missed The monthly incidence of parturition in these cases can be obtained with accuracy and the results agree closely with those of Dr Thompson (see accompanying table) The seasonal incidence of the onset of the anæmia cannot be determined with sufficient accuracy to give exact figures for each month However, the figures are sufficiently accurate to confirm Dr Thompson's findings that the highest incidence of the onset of the anæmia is during the late winter and spring

J W B FORSHAW

EFFECTS OF CARBUTAMIDE ON CARBOHYDRATE METABOLISM IN DIABETES

SIR,—Professor Bastenie's findings[1] seem to indicate that under treatment with carbutamide (B Z 55) both outflow of glucose from the liver, and resynthesis there, decrease We have studied, in the rabbit, the effect of carbutamide, with or without cortisone acetate, on the rise of blood sugar following the fall induced by 10 units of insulin given intravenously With insulin by itself, such a high dose ensures a significant rise of the blood-sugar—i e , outflow of glucose from the liver

Mild alloxan diabetes responds to carbutamide, but grave alloxan diabetes and diabetes caused by cortisone remain uninfluenced[2] Cortisone may inhibit the peripheral effect of insulin, but increases glucose production in the liver If carbutamide is really capable of decreasing the outflow of glucose from the liver, the post hypoglycæmic blood sugar rise must also be decreased

Male rabbits of the same breed, weighing about 3 kg , were used in the experiments We had previously observed, on administration of 10 units of insulin, a significant fall followed by a rise in the blood sugar level The effect of the insulin lasted four hours, and it rarely caused hypoglycæmic shock Blood sugar curves after giving 10 units of insulin intravenously are, accordingly, well suited for comparative examinations

Relatively high (therapeutic but not toxic) doses of carbutamide were administered—viz , 1 5 g daily for three to four days On the last day of the experiment, four hours after the morning dose, the insulin was given to the fasting rabbit The rabbits treated with cortisone acetate were given 5 mg intramuscularly at 8 A M , and 10 mg at 4 P M Hypoglycæmic attacks were seen in no case during the experiments

The morning blood sugar of the control animals (also during carbutamide therapy) was around 108 mg per 100 ml , and in the animals treated with cortisone acetate 142 mg per 100 ml , whether or not carbutamide was administered When carbutamide was given there were moderate rises as well as falls in the blood sugar in the early hours In the cortisone-treated rabbits, the average fall in blood sugar after insulin was 91 mg per 100 ml and the following rise 63 mg When carbutamide was given the average fall was 69 mg and the rise 68 mg The corresponding figures in the controls were 85 mg and 58 mg without carbutamide, and 60 mg and 49 mg with carbutamide

This means that, in spite of carbutamide treatment, there was a significant outflow of glucose from the liver

NEW METHOD OF PROMOTING LABOUR

SIR,—We have developed a new and natural method of promoting labour based on Verney's experiments with antidiuretic hormone in dogs[1,2] For this purpose we use an intravenous infusion of hypertonic saline solution on the assumption that this may stimulate the posterior lobe of the pituitary gland Our first results have been good

CASE 1 —A primigravida, aged 23 (last menstruation Aug 8, 1956), was admitted on May 6, 1957, at 6 A M The membranes had ruptured spontaneously half an hour earlier She had had an uneventful pregnancy A vaginal examination then revealed only 3 cm (2 fingers) dilatation She was put to bed without therapy At 1 15 P M another vaginal examination was made and revealed exactly the same situation as at 6 A M , she felt no labour pains, and we could feel no uterine contractions At 1 35 intravenous infusion of 1000 ml of a 2 5% *saline solution was begun and completed at 3 35* At 3 P M we felt the first weak uterine contraction The labour pains became progressively more frequent and stronger, and at 7 55 a baby weighing 3080 g (6 8 lb) was born spontaneously

CASE 2 —A primigravida, aged 33 (last menstruation July 26, 1956), was admitted on May 1, 1957, at 6 45 A M Labour *pains had begun at midnight, after an uneventful pregnancy* At 10 30 A M a vaginal examination revealed 3 cm (2 fingers) dilatation There were only weak contractions of a short duration At 4 45 P M a second vaginal examination revealed 4 cm dilatation, and at 7 45 P M a third vaginal examination showed the same situation , practically no contractions could be felt An intravenous infusion of 1000 ml of a 2 5% saline solution was administered from 8 45 to 9 20 P M At 9 P M the contractions began again, and became stronger and more frequent At 11 30, at full dilatation, the membranes were ruptured artificially, and at 12 25 A M a baby weighing 3060 g (6 7 lb) was born spontaneously

CASE 3 —A primigravida, aged 29 (last menstruation July 3, 1956), was admitted on April 4, 1957 Pregnancy had been uneventful despite the fact that she had had serious diabetes mellitus since the age of 4 (88 units of insulin a day) On April 7 we concluded that the child was dead, for the fœtal heart sounds suddenly ceased On April 11, and again on April 15, we tried unsuccessfully to induce labour by means of castor oil, quinine, and oxytocin On April 17 she was discharged At home she took stilbœstrol 20 mg hourly for 10 hours Since this also failed to bring about labour, she *was again admitted on April 23 From 3 30 to 4 20 P M we* gave an intravenous infusion of 1000 ml of a 2 5% saline solution At 4 30 P M we noticed the first contraction of the uterus, and these became progressively more frequent and stronger At 1 00 A M , at full dilatation, the membranes were ruptured artificially At 1 32 a macerated female fœtus weighing 3620 g (8 lb) was born spontaneously

All three mothers had a *slight sensation of thirst after* the infusion During and after the infusion the blood-pressure and urine were regularly observed We could find no proteinuria and only a slight rise in blood pressure

The injected hypertonic saline solution probably stimulated the neurohypophysis, *so that the posterior* lobe of the pituitary gland produced not only more antidiuretic hormone but also more oxytocic substance This may afford a powerful and natural means of stimulating labour We are now trying to work out a dosage scheme more thoroughly The method is, of course contra indicated in hypertensive toxæmia and cardiac disease

T L A DE BRUINE

HIRSCHSPRUNG'S DISEASE

SIR,—I was very interested to read the remarks of Mr Daintree Johnson and his colleagues (June 1) upon continence after abdomino-anal anastomosis It has always appeared to me that normal bowel control is an involuntary process and does not depend upon voluntary contraction of the sphincters or of the levator ani muscle Indeed, if what we are taught by physiologists is true, it is not possible to contract striated muscle for long periods

Normal continence depends upon a normal sensory mechanism in the lower rectum and the involuntary internal sphincter The latter thickened portion of the internal circular muscle of the bowel is the normal mechanism of continence The *voluntary external* sphincter is only brought into play to prevent the short lived sensation of the call to stool It can contract voluntarily for about a minute allowing " plastic adaptation " to occur in the rectum and the internal sphincter time to regain control

It is for this reason that abdomino anal operations may give disappointing results The reason why they may be successful is more difficult to understand

London, W 1

IAN P TODD

CARDIOGRAPHIC TECHNICIANS

SIR,—*Your annotation of May 18 draws attention* to the plight of radiographers Cardiographic technicians are much fewer, but their financial position also needs emphasis

In 1952 Mrs X was a trained medical secretary when appointed technician in charge of a very busy department In 1954 she was put on grade II of the cardiographic technicians' scale, £360 rising to £485 plus London weighting By 1956 a small award had increased the scale to £390 rising to £520 p a , plus London weighting My medical secretary at the hospital, twelve years her junior, was then earning £12 a year more (and medical secretaries are by no means overpaid in the health service) In view of the obvious disparity between her salary and her value to the hospital, it was twice *recommended to the Ministry of Health* that Mrs X should be given accelerated increments to her salary These recommendations were both rejected She would have preferred to continue in the hospital where she had worked for seventeen years, but she has recently accepted an appointment as medical secretary and cardiographer to an industrial firm, where her salary is £500 plus emoluments amounting to £39 per annum, and her promotion prospects are much better

Under the N H S , a trained cardiographer (who needs to understand her patients as well as her machines) earns no more than many shorthand typists of 19 in industry

While pressing our demands for increased remunerations for ourselves, it would be sad if, as a profession, we failed to press effectively for the improved *pay of* our technical assistants

POSSIBLE CONTROL OF RADIOACTIVE-STRONTIUM DEPOSITION IN BONE

SIR,—The accumulation in bone of radioactive strontium from nuclear explosions raises the question of whether it is possible to restrict the absorption of strontium by the body or to eliminate what has already been absorbed

The deposition of "calcium phosphate" in bone, in agreement with Robison's experiments,[1] can be interpreted in terms of the solubility-product principle, though not necessarily in terms of an initial deposition of trivalent phosphate Since the physical chemistry of strontium and calcium is very similar, it is reasonable to expect that the mechanism of their deposition will be the same It can also be reasonably assumed that strontium phosphate already deposited in bone—being, like calcium phosphate, "insoluble"—will be in a state of dynamic equilibrium with the surrounding tissues, in the same way as calcium phosphate This concept may be used to try to restrict the deposition of radioactive strontium or to remove existing deposits in bone

(1) Chemically, radioactive strontium and ordinary strontium are practically identical Consequently, for the limited amount which can be carried by a *saturated* transporting enzyme system, the higher the ratio of the concentration of ordinary strontium to the concentration of radioactive strontium, in a given intake sufficient to saturate the transporting system, the smaller will be the quantity of radioactive strontium eventually deposited Hence, addition of ordinary strontium salts to the diet, below toxic levels, should decrease the absorption of radioactive strontium, other factors being equal Accurate data concerning human toxic limits, however, are apparently unavailable

(2) For a limited and saturated phosphatase concentration—which may be expected to be responsible for the deposition of strontium in bone—the quantities of $[Ca^{++}]$ and $[Sr^{++}]_{ord} + [Sr^{++}]_{rad}$, by the solubility product principle, must also be limited. Now, the higher $[Ca^{++}]$, the more likely is calcium phosphate deposition and therefore the lower is the soluble phosphate ion concentration, this decreases the chances of strontium phosphate precipitation Hence, increase in the intake of calcium salts should decrease the uptake of both ordinary and radioactive strontium

People drinking very hard water or taking calcium salts should therefore deposit less radioactive strontium in their bones But absorption of calcium from the duodenum is dependent on pH (absorption takes place in slightly acid media, whereas in neutral or slightly alkaline conditions calcium phytate or phosphate may be precipitated) For this reason, people taking large doses of alkaline powders should be considered separately In such circumstances increased calcium salt absorption would require complex ions such as those found in the presence of citrates The presence of precipitated calcium phosphate in the duodenum, however, may not be without advantage, as will be seen presently

Some experiments I have performed suggest another approach Strontium ions are removed from solutions containing strontium salts when the solutions come in contact with calcium or magnesium phosphate, and the action depends on surface area and duration of contact The findings can be ascribed to initial adsorption followed by ion exchange and some precipitation of strontium phosphate This raises the possibility of removing strontium isotopes from the gut on a large scale and therefore of considerably restricting their absorption by adding calcium and magnesium phosphates to the diet

Methods of control involving increased calcium absorption are particularly applicable to the young, who take up considerably more radioactive strontium than older people, because in this case high calcium absorption is well tolerated When low calcium absorption is advisable, control may have to rely on gut precipitation and ion exchange methods

To remove existing deposits of radioactive strontium, other methods may be necessary Those used for the removal of lead and other metals give a guide Thus, lead deposited in bone can, by the injection of parathyroid hormone, be eluted and eventually excreted with bone calcium,[2] and it is likely that strontium elution will also follow A less drastic method involves the use of sodium calciumedetate, which combines strongly with heavy metals[3] Its administration leads to the formation of the lead salt, which is then excreted by the kidney[4] Sodium calciumedetate may reasonably be expected to form the radioactive strontium analogue and thereby hasten removal of strontium If so, the urine of persons treated in this way could be used to detect deposits of radioactive strontium in bone

Further details and physical biochemical considerations of the above and of the restriction of radioactive strontium transference in the food chain ending in man will be published elsewhere

HÆMOGLOBIN E IN A NEPALESE SOLDIER

SIR,—Hæmoglobin E has so far been found in Thais, Siamese, Indonesians, Veddas from Ceylon, Malaysians, Persians, and Philippinos Recently[5] it was not found in 199 Nepalese Indian soldiers In a study of the hæmoglobin types in Nepalese soldiers (Gurkhas) stationed in Malaya, one case has been found showing a combination of hæmoglobins A and E (hæmoglobin-E trait) On electrophoresis, using veronal buffer pH 8 8 by the evaporation-prevented technique,[6] the mobility was identical with that of an A and E sample supplied by Dr Lie Injo Luan Eng of the University of Indonesia Since this finding was recorded a similar example has been observed

The conclusion is warranted that hæmoglobin E does occur in Nepalese, but that its incidence is very low

NEW WAYS WITH TAR OINTMENTS

SIR,—Tar ointments are still regarded as widely useful in dermatology but their disadvantages generally are that they are "messy," and that "elegant" and smooth preparations are difficult and expensive to make Also tar ointments, because of the large and irregular tar particles, are frequently irritant

Carney and Zopf[7] described their experiences using 0 5% polyoxyethylene sorbitan monolaurate ('Teen 20'), which is a non-ionic surfactant, to help "break up" the tar particles He found that teen 20 (0 5%) and crude coal tar (1%) in zinc paste gave a very satisfactory ointment, in which the tar particles were uniformly small

For the past two years we have used a similar substance, cetamacragol, in tar ointments, and found it very successful With the aid of cetamacragol which is, I understand, widely used in cosmetic preparations, it is possible to break up the tar so that a very smooth and elegant preparation is obtained, and the tar can even be incorporated in ung aquosum if necessary These tar preparations are less messy to use than the ordinary ones, and spread more easily

We have used two types of base for the tar one very thick preparation in equal parts of Lassar's paste and 'Vaseline,' and a thinner one in ung zinc et ol ric

Keining and Weber[8] have advocated the use of 'Nobecutane' sprayed on as a film after tar has been applied. We have recently tried this on patients with only a few fairly large plaques of psoriasis, and have found it very useful. It not only keeps the tar off the patient's clothes, but also stops the clothes from rubbing against the patches, and it often makes tar treatments acceptable when they would otherwise be refused.

We have found that nobecutane works well if applied over the Lassar's and vaseline but not over ung. zinc oxide, on which it does not dry. Care must be taken to apply the nobecutane thinly and from a distance of about one foot.

I would like to thank Dr. Alice Carleton for allowing me to treat the patients and Mr. W. Trillwood for making up the ointments.

ACUTE SPONTANEOUS MEDIASTINAL EMPHYSEMA

SIR,—In your issue of March 9, Dr. Watts discusses five types of therapy for acute spontaneous mediastinal emphysema. A sixth which, I think, has merit when other techniques cannot be applied, is the inhalation of pure oxygen for a sufficient length of time to absorb nitrogen in the air dispersed through the mediastinal tissues.[9,10] This method was applied successfully to intestinal distension some 20 years ago, before the advent of the Miller-Abbott tube, and, in particular, for the absorption of the nitrogen in the air injected into the ventricles for encephalography. In the latter case, most of the injected nitrogen could be resorbed in three or four hours. Mention was then made of its possible application to mediastinal emphysema.

JACOB FINE.

CONSULTANT AND SPECIALIST

SIR,—In your leader of June 1 you stated that the consultant might get along well if relieved of some of his outpatients. As a general practitioner who held a senior-registrar post for four years, I have come to the conclusion that in a high proportion of cases the general practitioner could do without the outpatient department or the services of a consultant if he could have access to diagnostic facilities. The outpatient problem could thus be solved and result in an all-round saving in consultants. The general practitioner and the long-suffering patient would both benefit.

If the ability of the general practitioner received proper recognition and he was given better facilities for practice, more doctors might seek the comprehensive field of general practice and fewer the limited ground of the specialist, who generally sees only a part of every case. The whole standard of medical care might be improved and the cost of hospital care be greatly reduced.

Farnham Royal,
Bucks.
MARY HERFORD.

SIR,—I wish to condemn in the strongest possible terms the suggestion both in your leader and in the article headed "Reconstruction" (June 1) that a new grade of "specialist" of an assistant nature, with pay less than the consultant rate, should be introduced.

One of my main reasons for opposing this grade is your naive and implicit faith in the Minister of Health. The fact that he would use the grade to obtain a cut-price consultant service you say is baseless. In your article under "Reconstruction" you state that the representatives of the profession have ensured that the S.H.M.O. appointments have not been misused. In both articles you show yourself unaware of, or are conveniently casting a blind eye at, the abuse of the S.H.M.O. grade. Anyone who cares to look into the question can find scores of people in this grade, with higher qualifications and adequate training, who are doing work of a consultant nature and without supervision. It is ludicrous to suggest that the Ministry has been honest in its use of the S.H.M.O. position. A cut-price consultant service is at present in existence and its further extension should be vigorously opposed.

The answer to the problem posed under "Reconstruction" is simple—the creation of more consultant posts. By all means have assistant physicians, surgeons, &c., but pay them as consultants, and then, as you remark with regard to such posts in the North West Metropolitan Regional Hospital Board, the holders will work contentedly.

CUT-PRICE CONSULTANT.

SIR,—At the inception of the National Health Service general physicians and surgeons wisely refused to accept the grade of senior hospital medical officer (S.H.M.O.) in their specialties. In your leader you recommend the introduction of such a grade under a new name without any reference to the problems and frustrations experienced by S.H.M.O.s.

Their status has suffered all along from inadequate definition embracing, as it does, both part-time general practitioner and full-time hospital specialist. Most full-time hospital specialists have entered the grade as a step in the training ladder via senior house-officer, registrar, and senior registrar. Although almost all full-time S.H.M.O.s are doing consultant work when they apply for consultant posts, the strongest candidates against them are teaching-hospital senior registrars, lecturers, and research men. In numerous instances the S.H.M.O. fails to get the appointment.

It is extremely doubtful if any significant number of full-time S.H.M.O.s working as assistants in a specialty would wish to remain in that state. Not all will want to become departmental heads, but that should not prevent their reaching consultant status.

Much of the present difficulty might be resolved if the S.H.M.O., after four or five years' service, were given the right to make application to his hospital staff committee for a review of his grading. This review should be carried out by a committee of the regional board and the hospital concerned. The undue preference for academic distinction now shown by appointments committees can there be tempered by personal knowledge of the applicant's work and effectiveness in his hospital.

For the future, consideration might be given to the suggestion that no one be appointed consultant without having served as a S.H.M.O. for at least four years.

Peripheral hospitals can show that a 1 : 1 ratio of consultants to registrars is unnecessary and this should not be used as an argument against creating new consultants where needed.

The trained personnel to remedy the shortage of senior staff is available and with a little honesty all round the required establishment can be worked out.

S.H.M.O.

Obituary

GEORGE FREDERICK BUCHAN

M D Glasg, F R C P, D P H

Dr Buchan, whose death we announced last week, was medical officer of health for Willesden for thirty-five years But this formal description of his career is misleading, for it gives no idea of the extent of his influence on public-health thought and practice both inside and beyond this country

He was born at Kilmaurs near Kilmarnock, in 1878 and graduated M.B with distinction from the University of Glasgow in 1901 He at once decided to specialise in public health and the following year took the D P H He served his apprenticeship in his specialty in junior appointments in Birmingham and at Heston and Isleworth, and when in 1912 he became medical officer of health for Willesden, though he was still young in years he had a background of varied practical experience In those days Willesden still had areas of pleasant pasture and there was a forge in Neasden Lane The new M O H toured his district in a horse-drawn carriage The medical superintendent of the fever hospital visited his convalescent branch at Kingsbury on horseback The ambulances and school-buses were still drawn by horses The thirty-five years that Buchan spent at Willesden brought many changes The care of physically defective children of the maternity and child-welfare services were his special concern and the subject of many far-seeing reports to his council Willesden early offered immunisation against diphtheria to its school-children, home nurses to its invalids health centres to its families, a maternity hospital to its mothers Buchan was insistent that the agencies dealing with health and disease should be coordinated and his success in implementing this principle drew visitors from all over the world to Willesden He lost no opportunity to study work in other countries and his peace-time visits to the United States and Canada led to his being asked by the Canadian Wartime Information Board to visit the Dominion to tell the people there about Britain's health in war-time He was an honorary fellow of the Canadian and American public-health associations It was characteristic of his concentration on the future that when he retired in 1947 he closed his own record of his work at Willesden with the words "Little remains to be written but much has still to be done"

Elliott & Fry

But though Willesden was his parish his work was not circumscribed by its limits He lectured at Guy's Hospital, St Mary s Hospital, and the London School of Hygiene He took endless pains to arrange every detail of the programmes of the students sent to him at Willesden He examined for the Universities of Bristol and London He took a notable part in the revision of the curriculum for the D P H in 1946 He was a member of the Commission on Vaccination which sat from 1926 to 1930 and he was a member of the B M A. planning committee which reported in 1942 The Royal College of Physicians made him a member in 1927 and in 1933 he was one of the first medical officers of health to be elected to the fellowship For long he was also chairman of the council of the Royal Sanitary Institute, now the Royal Society for Health.

But his chief interest and perhaps the main channel of his influence was the Society of Medical Officers of Health He became treasurer in 1919 and laid down this office to serve as president in 1925, only to resume it Soon after the 1914–18 war he realised that if the expanding public-health service was to attract the right type of entrants, the conditions and remuneration of its appointments must be reconsidered, and for the next ten years he was the tenacious and moving spirit of the campaign sustained by the Society and the British Medical Association which ultimately led in 1929 to the recognition of the Askwith scale After Buchan retired from the treasurership of the Society in 1946 he continued to serve it as chairman of its council and in 1947 he was elected to its honorary fellowship Another task of his energetic retirement was the chairmanship of his local hospital management committee, and he conducted its business with his usual competence.

A L W, who for twenty years was associated with him in his maternity and child-welfare work at Willesden, writes

Buchan was a great teacher and trainer of medical administrators He drew a sharp line between administration and clinical medicine and did not expect his assistants to be expert clinicians nor his clinicians to dabble in administration It was the duty of his assistant medical officers to seek out those that appeared to require expert attention and to bring them before the appropriate consultant who attended regularly at his clinics and to see that the consultant's advice was carried out His medical officers were trained to be public health experts responsible for an area and he never approved of dividing them into M. and C W officers, school medical officers, and so on At this moment the most important measure to reduce maternal mortality is considered to be improvement in the standard of antenatal care Responsibility for seeing that a pregnant woman obeys instructions should rest on one person or clinic and the importance of following up defaulters is being stressed George Buchan stressed this in 1931 and any pregnant woman who failed to keep an appointment was visited the same day to find out the reason

Buchan was one of the clearest thinkers I have ever met However leafy the trees he saw nothing but the wood and not only steered a straight course through a problem but also convinced others without dominating them He had no use for woolly thinking yet he dealt with others whose brains were slower so gently that he rarely caused resentment

W J recalls that Buchan began his career among the giants of the public-health service

The two Hills, Bostock of Warwickshire and Eustace of County Durham Robertson of Birmingham, Hope of Liverpool, Shirley Murphy of the London County Council Newsholme of Brighton, and Newman of Finsbury to mention only a few were still in office Young though he was he soon took his place among them and proved himself of equal stature He held strong views regarding the status of the various kinds of health authorities and, indeed, of public health administration generally, and he was in no doubt that an area such as Willesden which he served with distinction for thirty five years, was well able to look after its own affairs without any supervision from a county council There was great competition among young people for appointments on his staff, and most foreign visitors studying British methods of public health administration were directed to Willesden where they found much to interest them In particular, the Ministry of Health made frequent use of his services and many a tentative official scheme was discussed or given a trial in Willesden He was a fluent speaker and a most determined advocate of any cause he had at heart He and the late Charles Porter of Marylebone together with James Fenton of Kensington (happily still with us) were a most formidable trio—not that they always agreed, but if they did they usually carried all before them

George Buchan was a striking figure—tall always immaculately turned out, and a lover of the good things of life He was a delightful and generous host If he promised to do anything he always did it in the appointed time and to the very best of his ability He was completely reliable Many members of the public-health service all over the world whom he had helped in one way or another though they will mourn his death, will be proud to have known and worked with him His elder brother, John Buchan of Bradford no less outstanding a character, survives him

Dr Buchan leaves a widow and a daughter

Births, Marriages, and Deaths

BIRTHS

SUDBURY —On June 9 at Brentwood to Mary (nee Sadler), wife of Dr J R. Sudbury—a son

DEATHS

FISHER —On June 4 at the Memorial Hospital Chipping Norton Oxford Donald Fisher M B

Notes and News

MEDICINE AND LETTERS

A collection of essays lately published[1] is united by the belief that, in medical writing, clear thinking must precede simple, concise exposition Dr R L Cecil discusses the editing of a medical textbook, and makes the point that editorship, as well as authorship, is tending to become multiple Plain words are called for by Dr Morris Fishbein and Dr Joseph Garland Dr Douglas Guthrie writes on medical history, and Dr J F Fulton on bibliography Dr F Marti-Ibanez gives an account of some famous men who combined the professions of medicine and letters Some essays are instructive, others discursive, all will interest those who know (or need to know) how great is the need for lucidity, precision, and conciseness in medical writing

NUTRITION OF URBAN CHILDREN

A joint committee on health policy of W.H O and Unicef has reported that the health of city children in rapidly growing countries is often poor The new populations have often crowded into fringe areas where sanitation is worse than in the villages The mothers acquire a harmful modicum of sophistication which leads them to abandon traditional ways of caring for children though they cannot follow modern ways In an Indian study infections and deficiency diseases were *found to* be commoner in urban than rural children

University of Cambridge

Lord Adrian, O M, has been elected vice chancellor of the university for 1957 58

On June 1 the following degrees were conferred

M D—G A Gresham, M C Joseph J J McMullan, David Scott

M B, B Chir—*C U Abengowe, *J P Clayton, *R M Pollock

* By proxy

University of London

Mr M J H Smith, PH D, F R I C, senior lecturer in chemical pathology at King's College Hospital Medical School, has been appointed to the university readership in chemical pathology at the school

Lung Function in Respiratory Illness

A postgraduate course on this subject will be held at Sully Hospital, Penarth, Glam, from Sept 9 to 13 Further particulars may be had from Dr Harley Williams, Tuberculosis Educational Institute, Tavistock House North, Tavistock Square, London, W C 1

Conference on Adoption

The standing conference of Societies Registered for Adoption s to be held on Oct 17 and 18 at the Church House, Dean's Yard, London, S W 1 Further particulars may be had from the hon secretary of the conference, Gort Lodge, Petersham, Surrey

Ciba Foundation

The first of the foundation's lectures on research on ageing will be given by Dr Nathan W Shock, chief of the gerontology branch of the National Institutes of Health, Baltimore, on Tuesday, July 9, at 5 P M, at the Zoological Society, Regent's Park, London, N W 1 He will speak on age changes in physiological functions in the total animal Admission will be by ticket only, obtainable free from the assistant secretary of the foundation, 41, Portland Place, W 1

College of Physicians and Surgeons of South Africa

In October this college will hold its first examinations for its fellowships in surgery, medicine, and obstetrics and gynæcology The South African Medical and Dental Council have in principle recognised these fellowships as "*additional qualifications*" Their titles will be F C S (S A), F C P (S A), and F C O G (S A) The council has approved the inclusion in the college of a division of obstetrics and gynæcology, equal in standing with the divisions of surgery and medicine It is intended to alter the title of the college to give effect to this change

National Hospitals for Nervous Diseases

Sir John Woods has been appointed chairman of the board of governors of the National Hospitals for Nervous Diseases, London

Poliomyelitis Vaccine for Malta

The minister of health for Malta has announced (*Times*, June 6) that the British Government has agreed to make poliomyelitis vaccine available for the island Enough vaccine to vaccinate 5000 children has been received and the same amount will now be supplied monthly

World Health Organisation

On June 15 a building erected by the *Danish* government in Copenhagen will be formally placed at the disposal of the World Health Organisation The building will house the regional office for Europe, which has hitherto been housed in the Palais des Nations in Geneva

Success of Campaign against Bovine Tuberculosis

Speaking at the Royal College of Veterinary Surgeons on June 5 (see *Times*, June 6) Mr D Heathcoat Amory, Minister of Agriculture, said that he hoped Britain would be free of bovine tuberculosis within five years Already nearly two thirds of the dairy herds in Britain were artificially inseminated and 90% of the population drank tuberculin tested pasteurised, or sterilised milk

MIDDLESEX HOSPITAL

Atrial septal defect (A S D) is the most frequent single congenital malformation of the heart encountered in clinical practice, yet its clinical diagnosis has only been accomplished during the past twenty years In 1875 Rokitansky gave a masterly account of the pathological anatomy of A S.D and its embryological basis, distinguishing two main anatomical forms—namely, defects of the septum primum and of the septum secundum Moreover, he stated explicitly that, in certain septum-secundum defects, the inferior vena cava opened partly or mainly into the left atrium, a fact which has been much ignored until surgeons became aware of it quite recently The association of A S.D with mitral stenosis was described by Corvisart (1811) and later by Lutembacher (1916), whose name is now linked with this combined lesion

Little was known of the clinical signs of A S.D until Assmann (1921) first identified its radiological features and thus paved the way to its clinical diagnosis When Roesler, in 1934, analysed 62 recorded necropsy cases, only 1 of them had been correctly diagnosed during life (by Maude Abbott) Within the next few years, the clinical diagnosis was being made with assurance (Bedford, et al 1941), but anatomical confirmation of the diagnosis, in this relatively benign lesion, was of necessity infrequent, and its distinction from various forms of pulmonary hypertension remained difficult The advent of cardiac catheterisation has now provided a means of verifying the diagnosis of A S D during life, and of elucidating its pathological physiology

Thus the stage was reached when surgical correction of A.S D could be envisaged, and in 1947 Cohn suggested suturing the right atrial wall to the margins of the defect In 1948 Murray, after experiments on dogs, closed an A S.D in a child by external suturing and in 1952 Bailey introduced the operation of atrio septopexy Another method of closing the defect without opening the heart has been introduced by Sondergaard and modified by Björk and Crafoord (1953), and by Edwards et al, (1955) Direct suturing of the A S D by opening the heart was introduced by Gross et al (1953) using an " atrial well," but this did not allow visual control Closure of the A S D under direct vision with the heart open was first accomplished by Lewis and Taufic (1953) employing hypothermic anæsthesia and this method has since been developed by Swan et al (1953 1955) and employed by Brock and Ross (1955) in this country and by Derra (1956) in Germany

To anyone who has studied the anatomical complexities of A.S D the advantages of direct vision must seem decisive, and now that hypothermic anæsthesia has become safe (Swan and Blount 1956) we believe that open heart surgery is the method of choice in the closure of uncomplicated A S D s

The indications for surgical treatment have to be considered in relation to the anatomical variety of the A S D and to the clinical findings and complications Therefore we shall briefly review the clinical features and complications encountered in 100 consecutive cases of A S D which we have investigated since commencing its surgical treatment at the Middlesex Hospital a year ago

Anatomy of Atrial Septal Defect

It is essential to relate the septal defect to the main anatomical landmarks visible within the right atrium—namely, the two caval openings, the eustachian valve the orifice of the coronary sinus and the tricuspid valve Unfortunately, all of these can rarely be identified in published pathological figures but Rokitansky's exquisite illustrations are an exception and his book is still our best guide to the anatomy of A S D However a purely embryological classification is inadequate for the surgeon, and the following anatomical classification is based on examination of pathological specimens on published necropsy findings, and on the surgical experience of ourselves and others

Atrio-ventricular defects (Persistent ostium primum , endocardial cushion defect , partial common atrio-ventricular canal) (Fig 1B)—This form of A S D overlies the tricuspid orifice and is crescentic in shape, its base being formed by the upper part of the ventricular septum and the attached mitral and tricuspid valves The aortic leaflet of the mitral and the septal leaflet of the tricuspid valve are often cleft and malformed, causing valvular incompetence An associated ventricular septal defect is common, as Rokitansky showed, and there may be a common atrio-ventricular (A-V) canal

Fossa-ovalis defects (Persistent ostium secundum)—The normal fossa ovalis is bounded above by a muscular annulus and its floor is covered by a membrane or so called valve which may be partly or wholly defective, or fenestrated Small defects occupy the upper part of the fossa ovalis but larger defects may extend to the orifice of the inferior vena cava in 8 of Rokitansky's cases the inferior vena cava opened either into both atria equally or mainly into the left atrium When the A S.D lies astride the inferior caval orifice its anterior limb may be continuous with the eustachian valve which thus forms the lower margin of the defect (fig 1E) In such cases, if the anterior and posterior margins of the defect are sutured together at operation, the vena cava will be shut off from the right atrium and so will communicate only with the left atrium The following forms of fossa ovalis may be recognised

(a) Defects of the upper part of the fossa ovalis below the annulus (widely patent foramen ovale) (fig 1C)

(b) Large fossa ovalis defects surrounded by a complete margin of atrial septum, and separated from the inferior caval orifice (fig 1D)

(c) Defects astride the inferior caval orifice which thus opens into both atria or mainly into the left atrium if there is a large eustachian valve (fig 1E) Occasionally small defects overlie the caval orifice leaving the fossa ovalis intact (Hickie 1956)

(d) Large fossa ovalis defects in which the posterior septal rim is lacking or rudimentary, so that the right pulmonary veins communicate virtually with both atria (fig 1F)

Superior caval defects (Sinus-venosus defect , high defect) (Fig 1G)—These are located immediately below and adjacent to the orifice of the superior vena cava, and above and separate from the fossa ovalis which may be intact or may contain a second defect Anomalous right pulmonary veins may open into the superior vena cava or into the right atrium adjacent to the septal defect

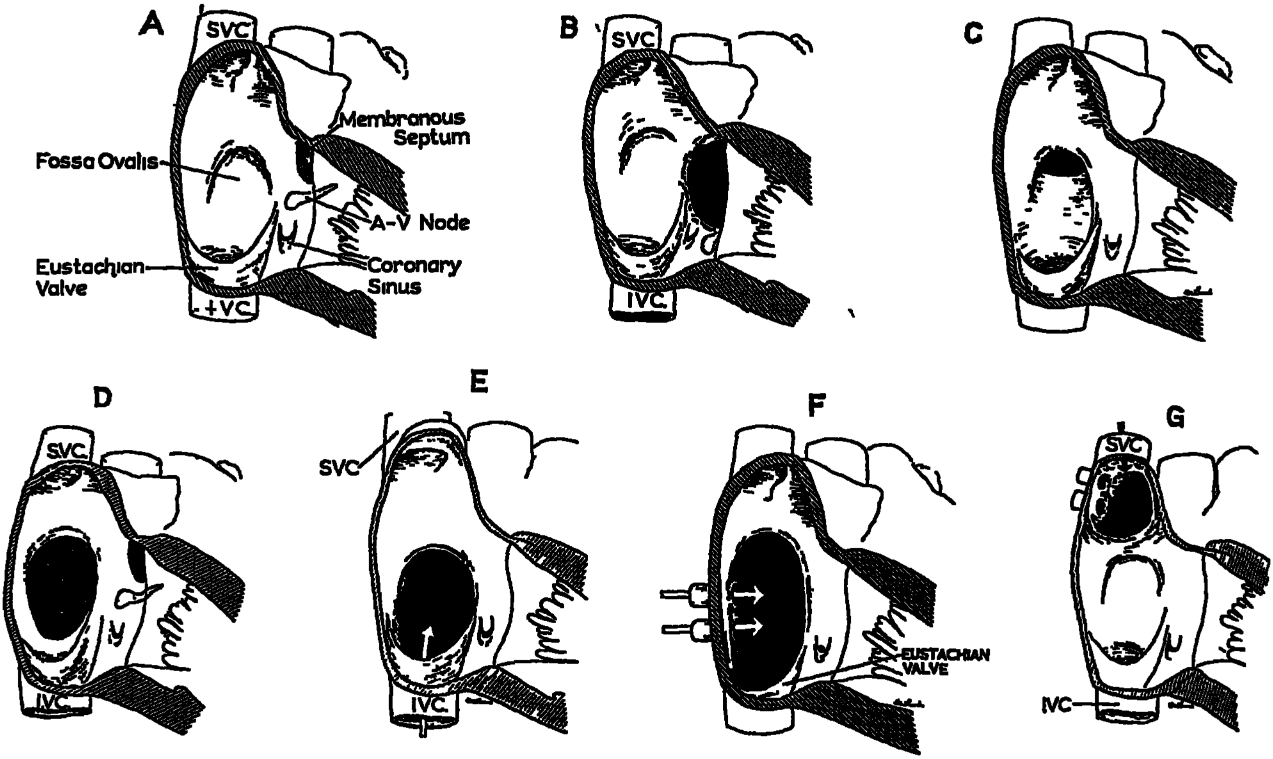

Fig 1—Anatomy of atrial septal defect, viewed from right atrium

(A) Normal atrial septum (B) A V type of defect (C) Widely patent foramen ovale (D) Fossa-ovalis defect with complete septal rim (E) Low fossa ovalis defect astride inferior caval orifice with large eustachian valve (F) Large fossa ovalis defect without any posterior septal rim, pseudo anomalous right pulmonary veins (G) Superior caval type of defect, showing entrance of right upper pulmonary veins

This type of A S D is probably less common than the A-V type, it was found once in 10 necropsies reported by one of us and was diagnosed in 3 of our 100 clinical cases It has been fully described by Hudson (1955), by Lewis et al (1955), and by Ross (1956)

Combination of defects—The three main anatomical types may occur in combination, thus an A V defect or a superior caval defect may be associated with a fossa-ovalis defect, or a single large defect may extend from the superior to the inferior caval orifice

Physiology

In uncomplicated cases, blood is shunted from the left to the right atrium so that the output of the right ventricle is increased, and the pulmonary blood flow usually reaches two to four times the systemic flow which is normal or slightly reduced As long as the vascular resistance in the lungs remains normal, the pulmonary arterial pressure does not rise appreciably unless the pulmonary flow is very large, when a moderate degree of hyperkinetic pulmonary hypertension results Obstructive pulmonary hypertension, due to an increased resistance in the small arteries, or to thrombosis of the larger arteries, or both, occurred in 15% of our cases As the vascular resistance rises, the shunt through the A S D is reduced, balanced, or sometimes reversed A bidirectional or reversed shunt is recognised by the appearance of central cyanosis, by the clinical signs of pulmonary hypertension, and by a reduced arterial oxygen saturation

Cardiac catheterisation was performed in 87 of our 100 cases, including all those submitted to surgery The diagnosis of A S D was confirmed by (*a*) a significant increase in oxygen saturation of blood samples from the right atrium and beyond compared with those obtained from the superior vena cava, (*b*) easy and usually repeated passage of the catheter from the right into the left atrium through the septal defect, accomplished in 50 cases

Estimation of the actual shunt through the defect must be regarded at the best as an approximation In 83 cases, the calculated pulmonary blood-flow was less than twice the systemic in 9, twice or more in 39, thrice in 21, and four times or more in 5 cases In 9 cases the shunt was balanced or reversed, and the arterial oxygen saturation reduced (63–89%) The pulmonary arterial pressure, recorded in 85 cases, was below 30 mm systolic in 59 cases, 30–50 mm in 15 cases, and over 50 mm in 11 cases in which the vascular resistance was elevated Anomalous pulmonary veins entering the right atrium or superior vena cava, or both, were demonstrated by catheterisation in 10 cases (11%)

Incidence

Wood (1956) found A S D in 18% of 900 cases of congenital heart disease investigated, of which it was the most frequent single lesion In regard to sex incidence, females predominated and constituted 69% of our cases In the past, A S D was not often diagnosed until adult life, but today it is more frequently recognised in childhood often at routine radiography, and 57% of Wood's patients were under twenty A recent paper entitled Atrial Septal Defect in the Aged (Coulshed and Littler 1957) indicates that it is occasionally compatible with longevity The ages of our patients were

Age (years)	1–9	10–19	20–29	30–39	40–49	50–59	60–69
Cases	11	23	28	12	13	9	4

Clinical Diagnosis

The usual clinical signs of A S D are now well established (Bedford et al 1941 Barber et al 1950, Leatham and Gray 1956) and therefore need only be enumerated briefly The cardiac impulse is of right ventricular type and often displaced to the left, there is a systolic lift over the outflow tract of the right ventricle and pulmonary artery, and in 20% of our cases there was a pulmonary systolic thrill The stethoscope reveals a pulmonary systolic murmur loudest in mid systole, sometimes a systolic ejection sound, and an obviously split second sound which varies little with respiration A diastolic murmur of relative pulmonary incompetence was heard in 20% of our cases and occurred when the pulmonary artery was grossly dilated or when there was pulmonary hypertension A short delayed tricuspid diastolic murmur was present in over half of our cases, and is due to an increased flow through the tricuspid valve The pulmonary systolic murmur is often audible at the apex The pulse is small or normal in volume, and the blood-pressure normal or rather low

Radiological findings include enlargement of the right atrium and ventricle, dilatation of the pulmonary trunk and main branches, and pulmonary plethora The aorta is usually small and the aortic knuckle may be invisible in the anterior view Exaggerated pulsation of the right ventricle and pulmonary trunk, sometimes accompanied by a hilar dance, is valuable evidence of a large shunt Calcification of the hilar branches was seen in 4 of our cases and in 3 a dense immobile right branch indicated thrombosis

The electrocardiogram showed partial or complete right bundle-branch block in 72 cases, and right ventricular hypertrophy without bundle-branch block in 18 cases In 8 cases the electrocardiogram was unusual, showing left axis deviation in 7, and right axis deviation combined with left ventricular hypertrophy in the chest leads in one case In 2 cases the electrocardiogram was normal

Clinical Diagnosis of Atrioventricular (Ostium primum) Defects

An A-V type of A S D may be associated with malformed mitral and tricuspid valves, with a ventricular septal defect, or with a common atrioventricular canal, and it is mainly by these complications that it can be recognised Its surgical repair is hazardous and usually needs more time than is available under hypothermia, so that its clinical recognition has become a major diagnostic problem

The A-V defect is not common, for it was found only once in 10 necropsies by Bedford et al (1941), and in 5 cases, verified by operation or necropsy, out of 85 cases investigated by Blount et al (1956), and its incidence at operation in America has been estimated at 10–15% (Brandenburg and DuShane 1956) We made the diagnosis of an A-V type of defect in 13 of our present 100 cases, and so far we have successfully excluded it in all cases submitted to surgery

Generally the heart enlarges early, symptoms appear in childhood, and pulmonary hypertension is common Those with a common A V canal usually die in infancy or childhood, but those with less complex types of lesion may attain adult life Rogers and Edwards (1948) mention 5 patients who survived the age of thirty, Bedford et al (1941) a patient aged forty four, and Cahen et al (1952) one aged forty-nine, and one of Rokitansky's attained the age of sixty one So an A-V type of defect cannot be excluded by age

The diagnosis has been discussed by Cahen et al (1952), by Blount et al (1956), by Brandenburg and DuShane (1956), by Toscano Barbosa et al (1956), and by Wakai et al (1956) In any case of A S D, an A V type may be suspected on one or more of the following grounds (1) unusual cardiac enlargement in childhood, (2) physical underdevelopment and mongolism, (3) pulmonary hypertension occurring below the age of twenty, (4) pansystolic murmur of mitral (or tricuspid) incompetence, (5) evidence of left ventricular hypertrophy in the electrocardiogram, (6) a left to right shunt at both atrial and ventricular levels, (7) bacterial endocarditis, (8) complete heart block

The most characteristic clinical finding is a loud pansystolic murmur, sometimes with a thrill, heard at the apex or left sternal edge, and due to mitral or tricuspid incompetence, or possibly to a ventricular septal defect There may be both systolic and diastolic murmurs, in which case mitral stenosis is simulated the term *faux syndrome de Lutembacher* has been coined (Cahen et al 1952) A left ventricular thrust may be appreciable at the apex-beat Bacterial endocarditis occurred in 1 of our cases and in 3 of those analysed by Rogers and Edwards (1948), whereas it is exceptionally rare in fossa ovalis defects

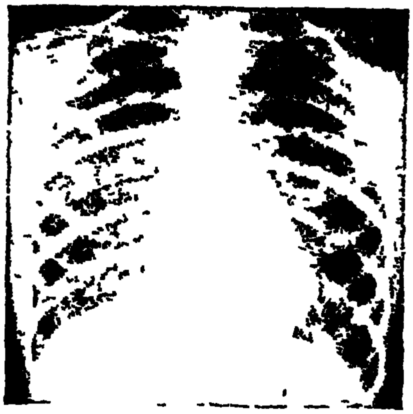

Fig 2—Radiograph showing localised dilatation of superior vena cava in case of high atrial septal defect.

The electrocardiogram showed *left* axis deviation and horizontal heart pattern in 7 cases, in 5 of which there was also partial right bundle-branch block in the chest leads In 2 cases the chest leads showed left ventricular hypertrophy as reported by Blount et al (1956) A prolonged P–R interval is common, left bundle-branch block and complete heart-block have also been reported (Cahen et al 1952)

Cardiac catheterisation may suggest a low atrial shunt, a shunt at both atrial and ventricular levels, or (we believe) a shunt mainly at ventricular level The catheter may pass readily into the left ventricle and its track through the A S D is said to be peculiar, though this should be interpreted with caution

Diagnosis of Superior Caval Defects

Radiographs may show a localised dilatation of the superior vena cava just above the right atrium (fig 2) Cardiac catheterisation may show arterialised blood in the superior vena cava compared with samples from the innominate vein, or samples from the upper part of the right atrium may be more oxygenated than those from the lower part Sometimes the catheter can be passed directly from the superior vena cava into a pulmonary vein (fig 3)

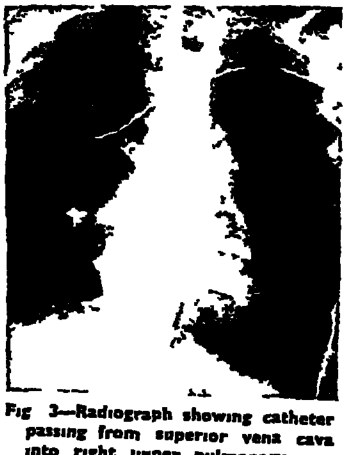

Fig 3—Radiograph showing catheter passing from superior vena cava into right upper pulmonary vein in case of high atrial septal defect

Complications of Atrial Septal Defect

Obstructive pulmonary hypertension occurred in 15 of our

100 cases, in 7 of which the shunt was reversed, in 3 balanced, and in 5 from left to right 2 with thrombosis and calcification of large pulmonary branches were not catheterised, and in another cyanosed patient the diagnosis was made by angiocardiography The pulmonary systolic pressures ranged from 50 to 118 mm Hg, and the vascular resistances from 3 5 to 38 units (1 unit = 80 dynes per sec per cm^{-5}) All showed clinical signs of pulmonary hypertension 2 patients were under twenty years of age and both probably had A-V defects 4 were between twenty and thirty, 3 between thirty and forty, and 6 over forty years Only 1 patient was submitted to surgery, namely a woman aged forty with a pulmonary systolic pressure of 75 mm and a vascular resistance of 3 5 units, but there was a 4 1 shunt from left to right and the hypertension was mainly hyperkinetic

Pulmonary stenosis —Wood (1956) found mild pulmonary stenosis in 10–15% of all cases of A S D , and it was diagnosed clinically or suspected from catheter findings in 11 of our 100 cases, in 2 of which the diagnosis was confirmed at operation However, we are sceptical of the diagnosis of mild pulmonary stenosis, based on a pressure gradient across the pulmonary valve, in cases of A S D with a large pulmonary flow when a condition of "relative stenosis" exists

Mitral stenosis —There is much discrepancy between post mortem statistics and clinical or surgical experience in regard to the incidence of mitral stenosis in A S D Thus mitral stenosis occurred in 4 of 10 necropsies but in only 4 of 43 clinical cases of Bedford et al (1941), and Burrett and White (1945) estimated its incidence as over 50% of all cases of A S D at necropsy It was diagnosed on clinical or other grounds in 6 of our 100 cases of A S D , in 3 of which the diagnosis was confirmed at operation

Atrial fibrillation was present in 10 of our cases, in 1 of which it developed after operation 5 of them had mitral stenosis, and all were over the age of forty except 1 with mitral stenosis aged twenty-four

Anomalous pulmonary veins opening into the right atrium or superior vena cava were recognised in 10 of our 100 cases at catheterisation and once at operation In 1 case where a right pulmonary vein was thought to open into the right atrium at catheterisation, it was found at operation to be just on the left side of the small posterior septal margin of the A S D It is especially in the high superior caval defects that anomalous right pulmonary veins are of surgical importance We are not considering here total anomalous pulmonary venous drainage which, of course, is invariably associated with an A S D

Clinical Course

According to post mortem statistics, the average age at death is between thirty six and thirty seven years (Burrett and White 1945), over half surviving the age of forty In A S D complicated by mitral disease, Bouvrain and Sibille (1954) give the average age at death as forty years

Although A S D is a congenital lesion, its consequences are acquired and develop gradually over the course of years as a result of the right heart being overloaded In uncomplicated cases, cardiac symptoms are usually mild or absent up to the age of twenty, after which some cardiac enlargement is common, and a grossly enlarged heart was found in 20% of our cases aged between twenty and forty, and in 60% of those over forty

Congestive heart failure occurred in 15 cases, 3 of them under thirty, and the remainder all over forty 5 of these have already been operated on, and another may become fit for surgery, but the rest are unsuitable because of their age and general condition, or of complications

To summarise, serious cardiovascular changes begin to develop after the age of twenty, and after the age of forty gross cardiac enlargement is present in over half

Indications for Surgical Treatment

With a heart lesion whose course is benign up to the age of twenty and sometimes even up to the age of forty the indications for surgical treatment are obviously related to the operative risk Wood (1956) expresses this view as follows "Until the mortality is under 5%, uncomplicated cases with 2 1 shunts should certainly be left alone" Accepting this view, we believe that today the operative mortality in uncomplicated cases should not exceed 5% at a centre dealing with a large number of cases and where a safe hypothermic technique is in routine use

It is true that published statistics indicate an overall operative mortality of about 10% for fossa ovalis defects, but these statistics are already out of date, and in properly selected cases the operation has now become far safer In A-V defects, of course, the operative mortality is much higher (probably over 50%), and we have not attempted to close them under hypothermia

The proper time to close an A S D is surely before the right ventricle and pulmonary vasculature have become irreversibly damaged, so that normal function may be restored to a relatively intact heart We believe, therefore, that uncomplicated fossa-ovalis defects with a shunt of 2 1 or more should be closed as soon as the diagnosis is established and preferably before the age of twenty, even in the absence of cardiac symptoms In practice, we are often faced with the problem of older patients with advanced heart disease, or even heart failure, and these patients have to be operated on unless there are contra indications to surgery

Mitral stenosis is no contra indication to closure of an A S D provided that the stenosis is relieved at the same time by valvotomy, and we have performed this combined operation in 3 cases with excellent results Slight pulmonary stenosis is likewise no bar to closing an A S D , and if necessary a valvotomy can be done at the same time

Pulmonary hypertension of hyperkinetic type, due to a large flow and without a seriously elevated vascular resistance, is no contra indication, but obstructive pulmonary hypertension is another matter When the shunt is balanced or reversed, closure of an A S D can only do harm Even when the shunt is still from left to right, closure of an A S D in the presence of serious pulmonary vascular disease removes the safety-valve action of a potential right-to left shunt during exertion and virtually reproduces a state of primary pulmonary hypertension Surgical experience indicates that closure of an A S D complicated by obstructive pulmonary hypertension is hazardous (Bolton et al 1957, Blount, personal communication), and we believe that the reward is unlikely to be great When an A S D is associated with systemic hypertension, as happens occasionally in older patients, its closure is likely to lead to left heart failure and is therefore, we believe, contra indicated

The A-V type of A S D is a complex anatomical lesion and its surgical repair is not only hazardous but must usually require more time than is available under hypothermia Atrio-septopexy has proved unsuccessful in this type of defect (Bolton et al 1957), so its closure requires open heart surgery by means of an artificial circulation Closure of high superior caval defects under hypothermia has been described (Lewis, et al 1955, Derra 1956) but we have not yet attempted it

To sum up, our contra-indications to closing an A S D under hypothermia are at present (1) A V type of defect, (2) reversed shunt with cyanosis, (3) obstructive pulmonary hypertension with high vascular resistance, (4) systemic hypertension, and (5) advanced age and poor general condition On one or more of these grounds 39 of our 100 cases of A S D were rejected as unsuitable for surgery

Surgical Experience

Closure of an A S.D by open heart surgery under hypothermia has been performed during the past year at the Middlesex Hospital in 40 patients (28 female and 12 male) aged six to fifty-five years

Age (years)	1–9	10–19	20–29	30–39	40–49	50–59
Cases	6	8	16	3	6	1

The heart was grossly enlarged (cardio-thoracic ratio over 60%) in 8 cases, considerably enlarged in 10 cases, and in the remainder moderately or slightly so, the right atrium being mainly involved 5 patients had congestive failure before operation, and 3 had atrial fibrillation Shunts, calculated in 38 cases, were less than 3 1 in 21 cases, 3 1 or more in 14, and 4 1 or more in 3 The pulmonary arterial systolic pressure was normal in 32 cases, 30–50 mm in 6 cases, and 75 mm in 1 case The pulmonary vascular resistance was normal in all but 2 cases where it was slightly elevated

All those submitted to operation had fossa-ovalis defects separated from the tricuspid valve, though some very large defects extended beyond the normal confines of the fossa ovalis, reaching the inferior caval orifice in 9 cases, and also the superior caval orifice in 2 There was no posterior septal residue in 2 cases

Hypothermic Anæsthesia

This was administered by Dr Sellick in all cases employing surface cooling and following the method developed by Virtue in Swan's clinic, with certain modifications (Sellick 1957) The important points in our technique are that an œsophageal temperature of 30°C at the time of circulatory arrest is regarded as ideal, and that rewarming by plastic water blankets is started as soon as the patient leaves the cold bath This degree of cooling permits circulatory arrest for at least seven minutes with safety and probably for a maximum period of ten minutes Neostigmine is injected into the coronary circulation via the proximal aorta before opening the heart and this we believe to be an important protection against ventricular fibrillation

During hypothermia the heart-rate was usually slow (about 40) Atrial arrhythmias were common and complete heart-block was sometimes encountered, but ventricular fibrillation occurred only twice and was due in both cases to technical errors In one it was brief and responded at once to electrical defibrillation, in the other it occurred when the heart was open and the circulation arrested, so that it could not be dealt with until closure of the A S D had been completed when it responded to electrical defibrillation combined with transfusion of blood directly into the right ventricle

Surgical Technique

The patient is removed from the bath after cooling to 31–32°C (œsophageal temperature) and placed supine on the operating-table, lying on and also covered by plastic water blankets through which water at 40°C is circulated by a pump Even with immediate rewarming, the temperature continues to drop another 0 5–2 C, and the maximum drop to about 30°C is timed to coincide as near as possible to the period of circulatory arrest Lower temperatures are unnecessary and predispose to dangerous ventricular arrhythmias

We have largely followed the technique introduced by Swan of suturing the defect under direct vision through the open right atrium during temporary arrest of the circulation Simple suture is sufficient to maintain closure; for, once the shunt has been eliminated, the tense and distended right atrium becomes retracted and flaccid so that the suture line is not under tension or likely to cut out

Operation

A bilateral thoracotomy is used for exposure of the heart A long transverse incision is made from one axilla to the other across the chest in the submammary region. The skin and underlying muscles are retracted to expose the fourth intercostal spaces and the pleural cavities are opened through these intercostal muscles Internal mammary arteries are secured between ligatures and the sternum cut across before opening up the incision with rib spreaders at each end of the wound.

The extrapericardial fascia and fat is divided and dissected free to the upper limit of the pericardium which is then opened along its left border and across the lower border as far as the level of the right phrenic nerve This triangular flap of pericardium is retracted to the right and sutured over the lung The superior vena cava is then encircled by a tape below the level of the azygos vein, a procedure which involves incision of a posterior pericardial fold which lies just in front of the right pulmonary artery The inferior vena cava is similarly controlled by a tape after incision of the pericardium where it is reflected on to the diaphragm The tapes are threaded through lengths of rubber tubing which, when pressed downwards, can act as tourniquets A special clamp is then placed with one blade through the transverse sinus and the other lying across the base of the pulmonary artery and the aorta (fig 4) A small incision is made into the lateral wall of the right atrium and the bare index finger inserted into the heart The edges of the defect are explored and the presence and size of the eustachian valve estimated The finger is passed through the defect into the left atrium where the mitral valve can be palpated, should it be stenosed valvotomy is carried out Next, the finger is passed through the tricuspid valve and through the right ventricle into the pulmonary outflow tract In nearly every case it is possible to feel the pulmonary valve itself and estimate any stenosis The atrial wall is clamped as the finger is withdrawn and the incision enlarged within the confines of the clamp to 2½–3 inches.

The heart is occluded from the circulation by tightening the tape tourniquets completely on both venæ cavæ, after which it is allowed to beat 10–20 times to empty itself of blood before the arterial clamp across the aorta and pulmonary artery is closed Neostigmine, 0 03 mg. per stone (14 lb) body-weight, is then injected into the aorta proximal to the clamp so that it reaches the coronary circulation, and the clamp is then shifted downwards

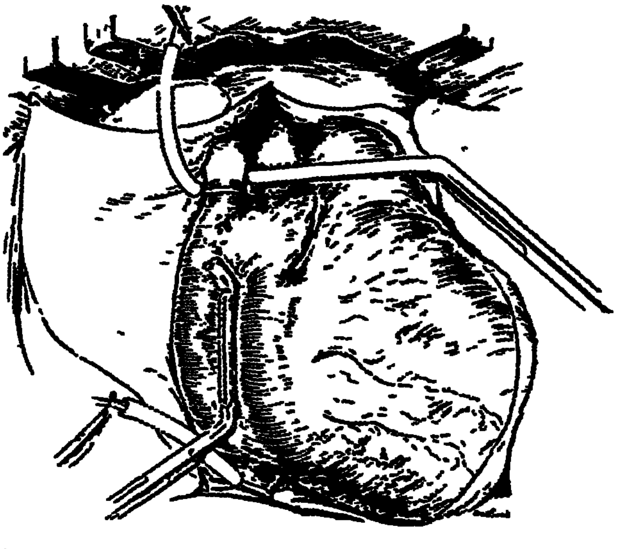

Fig 4—Method of arresting the circulation by tape tourniquets round both venæ cavæ and a clamp across aorta and pulmonary artery. Incision in right atrium controlled by clamp

to occlude the orifices of the coronary arteries The right atrial clamp is now removed and a *quantity of blood* gushes out which is sucked away while the edges of the atrial incision are retracted Continuous suction is required to keep the atrium free of blood so that the septum is visible The lower margin of the defect is then picked up by a suture (000 plastic or silk suture), and, using traction on this first stitch, the suture is continued upwards to the upper end of the defect, any bands or Chiari network can be included in the suture The end of this continuous suture is tied to a separate suture and two or three small interrupted reinforcing stitches are added

Before closure of the defect is completed, the anæsthetist inflates the lungs and distends the left atrium with blood, so excluding all air from the left heart The right atrium is then filled with Ringer's solution and one of the caval tourniquets is released As the right atrium quickly fills with blood, the edges of the incision are held upwards and clamped when all air has been expelled The second caval tourniquet is released and the clamp on the great arteries is removed The heart, which has been blue for some minutes, becomes pink in patches and as the circulation is restored rapidly regains its normal colour The incision in the right atrial wall is closed by continuous suture The pericardium is loosely closed and the chest incision is sutured after insertion of closed drainage tubes into each pleural cavity

The operation in most cases has been straightforward and the defect has usually been closed in four to five minutes Difficulties may occur in the case of low defects astride the inferior caval orifice without any lower septal rim If the defect is closed from above, a lower border or ridge is produced which overlies the caval orifice so that it communicates with both atria The lower edges of the defect must be sutured to the posterior margin of the caval orifice or to the adjacent floor of the left atrium so as to direct the caval flow into the right atrium Another problem arises if the lower border of the defect is formed by a large eustachian valve which is continuous with the anterior limb of the defect and merges into the posterior atrial wall (fig 1D) If the valve is included in the suture line, the defect will have been closed but the inferior vena caval flow will be directed entirely into the left atrium, causing central cyanosis

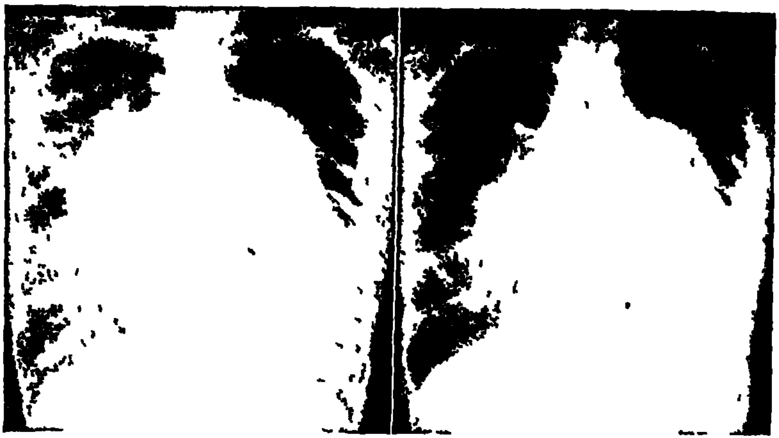
This happened in 3 of our cases

In the first, nothing unusual was noticed until some time after operation when central cyanosis developed

In the second, cyanosis was recognised on completion of the operation, the chest was reopened, and the circulation was again arrested for four minutes at 33°C On reopening the right atrium, the eustachian valve was found to have been *sutured into the edges of the defect* The stitches were removed, the valve cut across, and the defect was then reclosed

In the third case, after closure of a very large defect a postoperative examination of the arterial blood showed a reduced oxygen saturation suggesting that some of the inferior caval blood was entering the left atrium A second operation under hypothermia was undertaken later, and the right atrium was explored It appeared that the inferior vena cava had not been excluded from the left atrium, and the lower end of the defect was resutured However cyanosis persisted and seemed to be relieved by temporary occlusion of the vena cava The inferior vena cava was therefore divided and transplanted into the anterior wall of the right atrium, but the patient's condition *deteriorated and death resulted* At *necropsy*, it was found that the upper sutures had stenosed the superior vena caval orifice and directed it partly into the left atrium

In order to overcome some of the technical difficulties in cases of *low* defects, an obturator has been designed for insertion into the inferior caval orifice, which is thus held open instead of being buckled or narrowed by the tape *tourniquet* The *eustachian* valve is held *anteriorly* so that the lower edge of the defect can be more accurately defined This manœuvre is now carried out in all cases where the defect lies astride the inferior caval orifice and where a eustachian valve is palpated at preliminary digital exploration



(a) (b)

Fig 5—Radiographs (a) before and (b) six weeks after closure of atrial septal defect and mitral valvotomy Female aged 40 with Lutembacher syndrome Note diminution in size of right atrium

Postoperative Complications

Apical pneumothorax occurred in 10 cases but has now been avoided by the routine use of apical drainage tubes Small pleural effusions, mainly on the left side, developed as a rule but always resolved spontaneously Pericardial and pleuro pericardial friction usually persisted for seven to ten days after operation In one patient the rub persisted for three weeks with some pyrexia, and in another a febrile episode resembling the mitral post valvotomy syndrome occurred two months after operation Partial collapse of the left lower lobe occurred in 4 cases, paralysis of the left diaphragm in 1, and a transient Horner's syndrome was observed twice Postoperative abdominal pain, sometimes accompanied by nausea and vomiting, and suggestive of mild ileus occurred in 4 cases and these symptoms have been reported by others Cerebral symptoms occurred in 2 cases, one described later, and also in the last patient to be operated on who is improving

Postoperative arrhythmias were recorded in 15 cases—namely, atrial fibrillation in 3, atrial flutter in 3, ectopic supraventricular tachycardia in 6, and nodal rhythm in 3 cases Sinus rhythm was restored in all but 2 in one with a very large heart fibrillation has persisted, and in another recent case flutter is still present

Results

There was no operative or postoperative mortality apart from the one fatality, after a second operation, already described The immediate benefit to those with very large hearts and heart-failure or serious cardiac symptoms was remarkable Failure disappeared, effort tolerance increased, and the heart became much quieter There has also been a gain in weight and improvement in general health in poorly nourished patients In those without seriously enlarged hearts, the benefit of closing the A S D can be assessed only in future years, but most of them are less conscious of an overactive heart and feel better There is every reason to expect that restoration of normal cardiac function will prevent the progressive cardiac and arterial changes which usually occur in older patients, and that their expectation of life has been prolonged

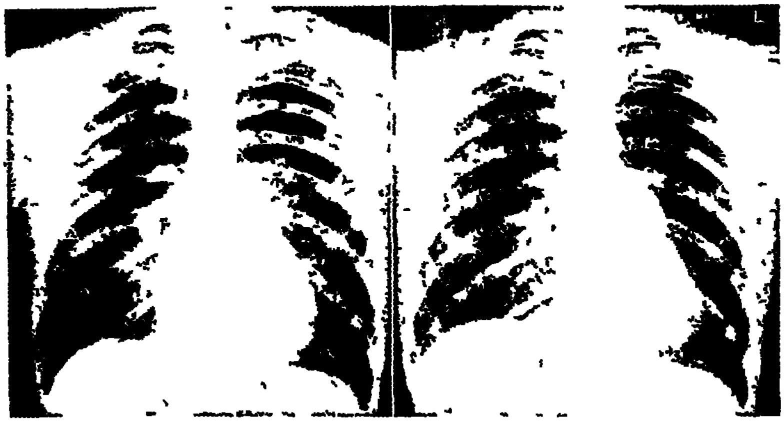


Fig 6—Radiographs (a) before and (b) six months after closure of atrial septal defect Male aged 20

There were two unsatisfactory results in which, as already stated, the inferior caval blood was deflected into the left atrium in closing low septal defects

In one, a boy aged 15, nothing untoward was noticed until after operation when there was a transient cerebral disturbance followed by tachycardia Four months later, there was slight central cyanosis and clubbing of the fingers, and pyrexia due to infected tonsils Following tonsillectomy, an angiocardiogram was performed, contrast medium being injected through a catheter into the inferior vena cava This showed that most of the inferior caval blood entered the left atrium The patient is now convalescing from tonsillectomy after which it is planned to operate again and resuture the A S D

The second case has already been described

Postoperative cardiac catheterisation has so far been performed in 12 cases In 7 of them catheter findings were completely normal and in 3 of them compatible with an insignificant residual shunt In 2 cases appreciable shunts persisted, in one a shunt of 9 litres per minute was reduced to 3 litres, and in the other an 11 litre shunt to 4 5 litres Curiously enough the last patient was the one who showed most dramatic benefit from operation Before it, she had a very large heart and was completely incapacitated by failure, but her heart became much smaller and she is now back in full time employment Anomalous pulmonary veins, recognised at operation in this case, were directed into the left atrium, but others may have been overlooked

Postoperative Clinical Signs

The most obvious change was that the overactive heart became much quieter, the right ventricular systolic lift diminished or disappeared and the apical impulse became less forcible A pulmonary systolic thrill, present before operation in 7 cases always disappeared and the systolic murmur diminished or sometimes disappeared Splitting of the second sound usually became closer or confined to inspiration, but in 10 cases wide splitting persisted unchanged The tricuspid diastolic murmur always disappeared, but a mitral diastolic persisted in 3 cases with mitral valve disease A pulmonary systolic ejection sound when present always persisted, and in 9 cases it only appeared after operation It was difficult to compare heart size in preoperative and postoperative chest films, owing to cardiac displacement and a higher level of the diaphragm postoperatively, but large hearts became obviously smaller and the right atrium was always less prominent (figs 5 and 6) Changes in the electrocardiogram often indicated a diminution of right ventricular predominance in chest leads V1 and V6

Summary and Conclusions

The anatomy of atrial septal defects is described with special reference to their surgical repair

The clinical features, hæmodynamic findings, and complications in 100 consecutive cases of atrial septal defects are briefly given and the indications for and contra indications to surgical treatment are discussed

Uncomplicated fossa-ovalis (ostium-secundum) defects can be closed under hypothermia with little operative risk, and this should be done preferably before the age of twenty years, when the heart and pulmonary vessels are intact, but even after the age of forty, and when the heart is grossly enlarged, operation may still give good results

Atrio-ventricular (ostium-primum) defects cannot safely be closed under hypothermia, and their clinical diagnosis is discussed Obstructive pulmonary hypertension with a seriously elevated vascular resistance is regarded as being usually a contra indication to surgical closure of an atrial septal defect

The closure of atrial septal defects by open heart surgery under hypothermia is described and the results of operation in 40 cases are given There was only one fatality, following a second operation undertaken to resuture the defect In another case, an unsatisfactory result was due to deflection of the inferior vena cava into the left atrium In the remaining cases the immediate results have been satisfactory

We are indebted to numerous colleagues for referring cases of A S D to us, especially to Dr J W Brown and Dr R Kemball Price Some of our cases were investigated at the National Heart Hospital and we are grateful to Dr Paul Wood, director of the Institute of Cardiology, and to Dr N A J Hamer and other registrars for their valuable help and cooperation We also wish to thank Mr J W Jackson who has assisted at all operations, Mr E Bridger, chief cardiological technician, and Miss E Hewland, medical artist, who have always been present in the operating theatre

SLEEP AND WAKEFULNESS IN THE ARCTIC

H E LEWIS *
B Sc, M B Cape Town
DIVISION OF HUMAN PHYSIOLOGY, NATIONAL INSTITUTE FOR MEDICAL RESEARCH, LONDON

J P MASTERTON
M B Glasg, D Obst
HOUSE SURGEON, THE HOSPITAL FOR SICK CHILDREN, LONDON

ON the British North Greenland Expedition of 1952–54 there was an opportunity to study the effect of the polar environment on the twenty nine men who were exploring an area at about latitude 77° N, some 800 miles from the North Pole (Lewis and Masterton 1955) There were two laboratories, one at the edge of the inland ice at Britannia So, and the other (a smaller station "Northice"), almost 300 miles out on the inland ice and manned by three scientists

There are two main climatic phenomena in the polar circles—the extreme cold, and the periods of light and darkness which are seasonal and not diurnal as in the lower latitudes At 77° North there is a summer period of continuous sunlight and a winter period of darkness, each lasting about 3 months

The effect of the environment was studied on the sleep pattern of men used to a diurnal cycle, observations being made on the number of hours slept over the seasons, the effect of specific duties, and the relationship of disturbed sleep to the taking of naps In this study artificial situations were not imposed experimentally, the records being made in natural surroundings

Each member of the expedition was issued with a specially printed sleep-card (fig 1) which he filled in daily At the end of every month the completed card was exchanged for a new one, and at the end of the expedition the information was transferred to a punch card system and the results extracted, each month being adjusted to 31 days Sleep/wakefulness patterns were plotted for groups and individuals (fig 2) after the method adopted by Kleitman and Engelmann (1953)

Periods of sleep not longer than 3 hours, and separated by at least 1 hour from the main sleep of the day, were defined as "naps" This implied that a nap was "sleep taken with the clothes on" It could usually be identified on the sleep card as an isolated line Interrupted sleep appeared on the cards as a discontinuous line on which the interruptions represented the time awake Recording of either naps or interruptions was not difficult, for the cards were usually well-documented with regard to time, frequency, and suggested causes of sleeplessness Examples are seen in fig 1

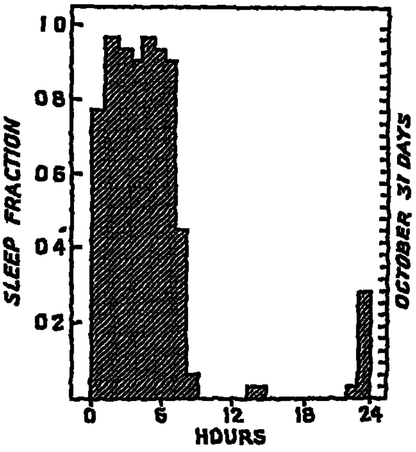

Fig 2—Sleep/wakefulness pattern derived from the sleep-card (fig 1) The hatched areas represent the fraction of the month spent in sleep There is a steep descent of the line which separates sleep from wakefulness, and the hours after 0900 are not involved in sleep, except for the nap at 1300 (After Kleitman and Engelmann 1953)

Results

The results are shown in figs 3–9

Total sleep —In a group of five men whose sleep cards were complete for 24 months, the mode was at 229 hours per month (7 4 hours sleep per night) If all available sleep-cards from the whole expedition were included, the mode was at 220 hours per month (7 1 hours per night) (fig 3) The mean sleep of individual subjects was 7 9 hours per night (S D =0 82) There was no relation between the age of the subject and his hours of sleep

Time of awakening —There was great variation in the time at which members awoke (calculated as a monthly mean) Greenwich Mean Time (G M T) was observed throughout, the local noon being 1430 hr G M T In the first 2 months the time of awakening ranged between 0600 and 1000 hr, but as the winter proceeded the range increased until the month of January which showed the widest dispersal from 0800 to 1600 hr In early spring the range contracted again, but in midsummer became large, from 0500 to 1300 hr In the autumn there was contraction The variations were considerably less in the second year, but the mean time of getting up was later—namely, nearer 1200 hr Fig 4 shows that the variation of awakening was due to the random time at which individual members awoke

Time of going to sleep —In the first two months the times of going to sleep were between 2100 and 0100 hr,

Fig 1—Sleep-card This shows the typical distribution of sleep during a month for a man in the U K.

---

* Previously Lecturer in Physiology, University College, London

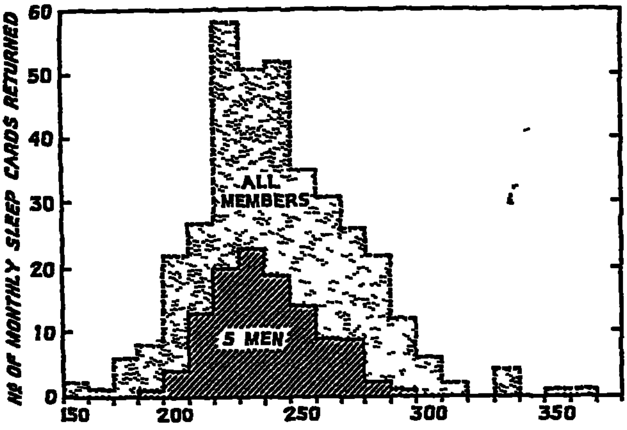

Fig 3—Distribution of total monthly sleep of all members, and of a group of five whose cards were complete for 24 months

with the onset of the winter this range widened, so that in January the mean times ranged from 1300 to 0300 hr The range contracted in the spring, but in the summer it broadened again to 1900–0100 hr The pattern was repeated in the second year

Fig 4 shows that the variation in the group was due to individuals' random time of going to sleep, likewise calculated as a mean time over the days of each month

Effect of continuous darkness—Sleep-wakefulness graphs, drawn for the group over the winter months, showed deviations from the conventional pattern illustrated by fig 2 An example is the card shown in fig 5

Effect of continuous sunlight—In the summer months there was rearrangement of sleep An example is shown in fig 6 As with the winter darkness, the total sleep per month was not appreciably altered

Effect of specific duties—Radio and weather observation were two duties at 0600 hr Fig. 7 shows the differing sleep rearrangement in two men (A and B) who had to be awake at that time As the season progressed, B (but not A) took the bulk of his sleep each night after the duty A slept 1·4 hours longer than B (nightly average)

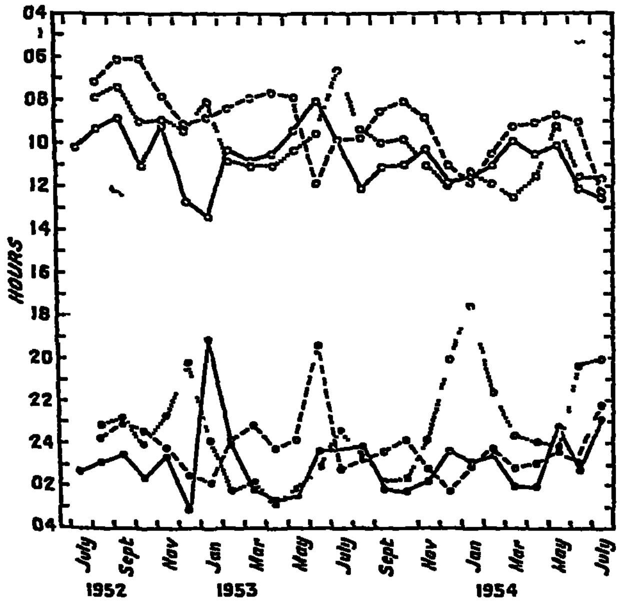

Fig 4—Times of awakening and going to sleep for three individuals Open circles represent times of awakening closed circles times of going to sleep The variation of the times for the group is seen here to be caused by variation in individuals' times

Monthly variations—As a group, the members slept longer in the first 12 months than in the second, a statistically significant difference of 0·4 hours a day, but this did not apply to individual subjects month by month for the 2 years

There was also a slight though statistically significant difference between the months, the general tendency being for longer hours in the autumn and shorter in the spring (fig 8) The pattern was repeated in the second year, though at a slightly lower level

Interrupted sleep—Fig 9 shows the monthly mean number of interruptions for the group There were fewest interruptions in August, 1952 Increases above the August level occurred in the winters of the 2 years The increases were smaller in the summer months, except for July, 1952, which gave a mean of almost 36 interruptions per man, due to seasickness on the voyage to Greenland

Naps—The monthly mean for the expedition was lowest in August, 1952, and in September, 1953 There were peaks in mid-winter, especially January, when the number of naps per person per month was over 25 (fig 9) In individuals, however, the taking of a nap did not closely follow nights of interrupted sleep

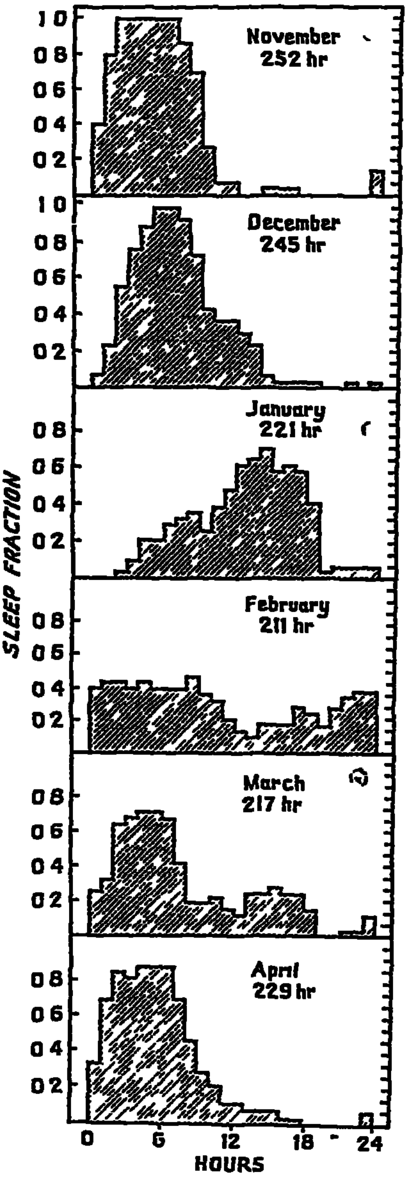

Fig 5—Sleep/wakefulness graph for one member

DISCUSSION

Living Arrangements

The cycles of sleep and wakefulness in man are determined largely by the influence of the community (Gesell and Amatruda 1945), which in turn has derived its pattern from the diurnal solar cycle of light and darkness Apart from other considerations it is economical—in the broadest sense—to sleep during the darkness and be active during the light hours

This is a perfectly reasonable arrangement in almost all parts of the globe In the polar regions, however, the period of light and darkness is not diurnal but seasonal

Visitors to Northern Norway during the summer often comment that there is much activity in the streets in the broad daylight of midnight but a careful study of the

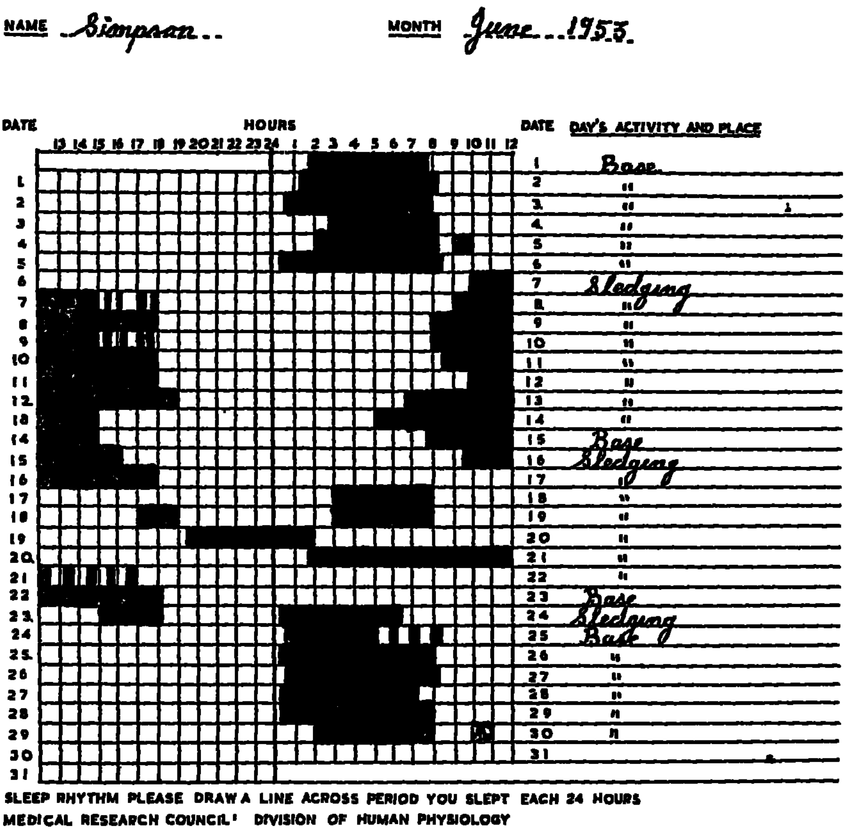

Fig 6—Sleep card for a member who slept mainly between midnight and 1000 at the base laboratory, but between 0800 and 1800 when sledging. He preferred to travel during the "night" when the snow surface was harder.

habits of the residents of Tromsø (Kleitman and Kleitman 1953) showed that this was not the case, and that in fact communally they did conform to the diurnal sleep/wakefulness pattern. The activity in the streets is usually associated with the departure of a ship, and soon afterwards the town is completely quiet, for they keep much the same hours as people in the rest of the civilised world.

There was confirmation of this when the ship of the British North Greenland Expedition arrived in Reykjavik, Iceland. It was broad daylight, and the members were surprised that the important harbour was so deserted and that the authorities did not immediately send a pilot when the siren was sounded. It was only then realised that the time was 2 A.M. and well out of normal working hours.

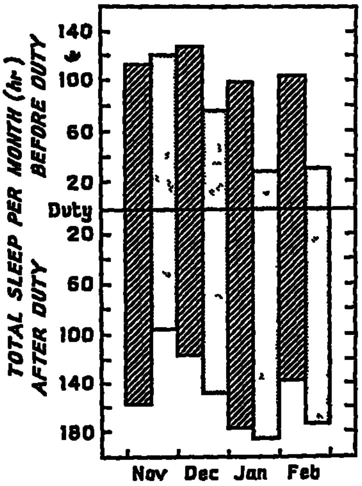

Fig 7—Relationship of sleep in two members to the 0600-hr meteorological duty at the Ice Cap Weather Station. A, winter 1952 (hatched). B, winter 1953 (stippled). As the season progressed, B took the bulk of his sleep each night after the duty, but A kept to his earlier pattern. On average, A slept 1.4 hours longer each night than B.

It appears, therefore, that despite months of darkness and of light the diurnal pattern is maintained, since the community is organised on this pattern. But if there is little or no control by community habit it is interesting to observe what happens to the sleep/wakefulness pattern of members. This might represent a truer *physiological* state of affairs than the conditioned pattern which reflects rather a *sociological* picture.

On the British North Greenland Expedition the men did not live as a strictly organised community. As long as the scientific programme or domestic work of the day was done, there was no reason why one should not take sleep at any time during the 24 hours. Some of the scientific programme required attendance at definite times, such as the weather observation and radio, whereas others required work to be completed over a period of months without necessarily a daily routine. The medical research programme was carried out at times convenient for the other scientists, without interfering with their routines.

In the winter their activity consisted mainly in calibrating and checking apparatus indoors, though a few men spent 2–3 hours outside tending the dogs. Physiological research was probably most active at this time, since most subjects were under one roof. Except for fortnightly estimations of basal metabolic rate early in the morning, their sleep was not interfered with.

Conditions of sleep were comfortable at base. There were iron bedsteads, each of which was covered with sponge rubber ($^1/_2$ in. thick) and a sheepskin. Each man had two down sleeping bags, and to make the beds more comfortable some slept on top of their spare sleeping bags, or other soft material such as parachute cloth, unused clothing, or canvas.

On the trail the men put one sleeping bag inside the other and lay on the sheepskin, which was placed directly on the snow. Inflatable air mattresses were not popular, because of their undue springiness. During cold weather, perspiration condensed and froze in the sleeping bags and sheepskins, considerably reducing their insulation; but the men slept well and only occasionally complained of sleeplessness due to cold.

During winter the men complained of sleeplessness which they attributed to comparative inactivity and to the stuffiness of the sleeping quarters. Windows and doors were kept shut to preserve the warmth, and as the building was draught-proof the air was so stagnant that tobacco smoke remained in layers at about 7 ft. There was a temperature gradient of 10°C between the air at the level of the upper and lower bunks, the upper often being uncomfortably hot.

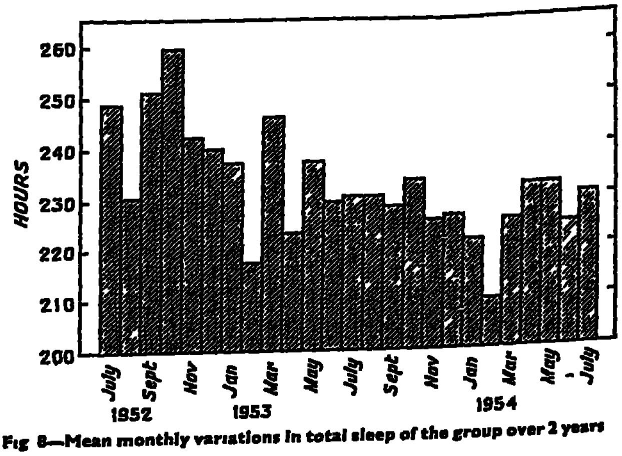

Fig 8—Mean monthly variations in total sleep of the group over 2 years

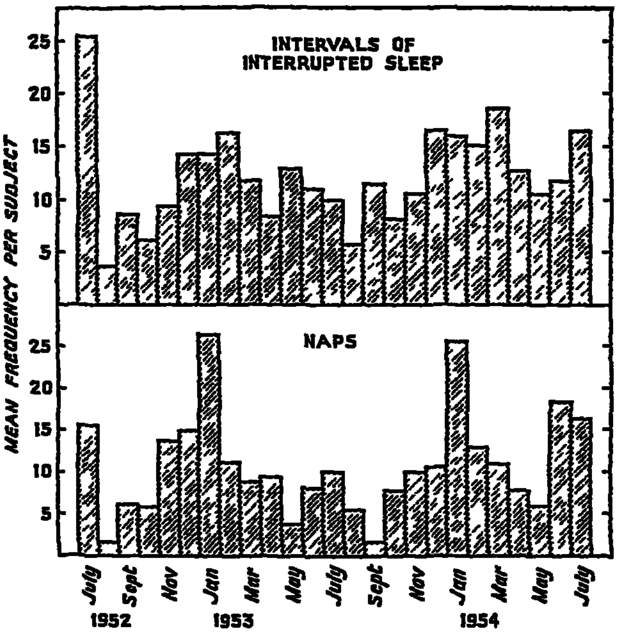

Fig 9—Intervals of interrupted sleep and naps

During the summer at the base laboratory complaints were made that the continuous sunlight made it difficult to sleep, even though there was outdoor physical work to tire the men Some curtained the window of their bunks, others blindfolded themselves One member asked for sleeping-tablets occasionally throughout the year, but this was not permitted. In spite of the complaints the total sleep of individuals was not significantly altered

Cooking duty was the main domestic chore, and it involved two men for a week at a time For the twenty other men the day began when the cook called them for breakfast About a quarter were usually awake when he came round, of the others, half responded at the slightest touch and half needed violent shaking Though mealtimes were set, this did not imply that the men had to be up and about after breakfast, and sometimes they went back to sleep—if they had been working late or celebrating the night before There was little social pressure to encourage being up early

During the winter men occasionally got up in the middle of the night to cook a snack, since all were familiar with the kitchen During the summer they would often be up very late, not realising the time, because of the continuous daylight, usually they cooked a snack before retiring, and this might represent “ breakfast ” if they chose to sleep late These examples show that they did not allow meals to interfere unduly with their chosen sleep habits Kleitman et al (1937) studied the effect of late snacks, which they found to produce a slight decrease in body movements during sleep, but no effect on the duration of sleep

If a man woke late he would have difficulty in getting to sleep at the conventional hour that evening, and would stay up working or reading until the early hours Then he would go to bed sleeping till next afternoon This arrangement tended to progress until the subject found that he was now on “ night shift ’ because he had indulged in sleep/wakefulness cycles of duration longer than 24 hours There were no landmarks of light and darkness to warn him that he had also lost a calendar date

The opposite might have been expected during sledging, because of the pattern of 8 hours’ work and 8 hours’ rest—namely 4 days’ activity in 3 In fact, this was not so Awakening on the trail was usually spontaneous, or by one’s sledging companion Other forces might include hunger, cold, a full bladder, or noise from the dogs Alarm clocks were used only occasionally

Other aspects of expedition life have been described elsewhere (Lewis 1954, Taylor 1955, Simpson 1957)

Methods

One of the approaches in the investigation of biological rhythms is to alter artificially the rhythm of the external environment—e g , to see what happens to men on an 18-hour or a 28-hour day (Lindhard 1910, Kleitman and Kleitman 1953, Lewis and Lobban 1954)

On the British North Greenland Expedition this was impracticable because many of the scientific duties involved radio and meteorological reports at strict G M T Time signals from the British Broadcasting Corporation were used continually to check chronometers, an essential part of navigation Because of this constant preoccupation with clock time, the observational approach was used, and though the filling-in of sleep-cards did rely on memory it was recent memory The men cooperated well

Seasonal Variations

During the times when the sleep patterns were disrupted, many men were going to sleep when others were getting up (fig 7) The casual observer would conclude that the men asleep were lazy, but the sleep totals showed that this was not so, and the impression of oversleeping was not confirmed Even though “ demand sleeping ” was possible (i e , whenever a man felt so inclined) the number of hours taken was not excessive and corresponded to the customary 8 hours

The environmental influences in Greenland affected the duties of the expedition During the darkness there was comparative inactivity and greater opportunity for sleeping , the summer was the season for outdoor work It was expected that more sleep would have been taken in the dark inactive period, but the difference was small Nor was there a significant change in the sleep totals during the periods of activity Less sleep was taken in the second year, but with little variation between months

Disrupted Sleep and Naps

In the first year, during the late summer and autumn, all men worked very hard to unload the aircraft and establish the base Because of near exhaustion each day, there were no sleep problems, but after this activity was over, with the onset of winter, some men started complaining of sleeplessness, and the taking of naps became a feature It is a common observation that, in ordinary circumstances of living, if after a sleepless night one takes a long nap, one’s sleep for the following night tends to be disturbed In Greenland there was a seasonal change in the number of sleepless nights, higher figures being found in winter and (to a lesser extent) summer In the other seasons the number of interruptions was very small.

An identical seasonal variation was found in the incidence of naps From this it might be presumed that they were taken to compensate bouts of interrupted sleep, but there was in fact no relationship. On the monthly basis only one nap was taken for every twenty interruptions of sleep, and there were only rarely direct coincidences of a nap within 48 hours of disturbed sleep In three members there were no coincidences at all

Specific Duties

It has been mentioned that the British North Greenland Expedition was a community only partially “ organised ” Provided the routine chores were done and one’s scientific programme was carried out, one’s spare time was not disciplined With such a background it is interesting to observe the effects of specific regular scientific duties on the sleep/wakefulness patterns of the members concerned For example, every morning at 0600 hr there was a weather observation, and this had to be transmitted by radio It was possible to compare the patterns of two meteorologists for 1952 and 1953

For one (A) in the winter of 1952, the duty caused his sleep to break up into two equal lengths, a pattern unchanged over 4 months In the following year, in identical circumstances, the other (B) showed that as the winter progressed he was taking most of his sleep after the meteorological duty—i e, he stayed up for this and then took his main sleep (fig 7)

It was possible also to study the sleep patterns of two radio-operators

During winter at the Northice, where he was one of three men, one radio operator took about a third of his sleep before the 0600 hr duty and the remainder afterwards, including a great number of naps at haphazard times, so that over a month almost every hour in the 24 was, at some time or other, used for sleep The next year he did the same duty at the main laboratory where over twenty men were working under conditions of greater communal organisation Despite this change of environment, his sleep pattern was disrupted as in the previous year If, however, the expedition had exerted social pressure on the members' off duty times, he would probably have conformed to the community timetable

His patterns may be compared with those of the other radio operator, who went to bed at a conventional hour, about midnight, woke just before 0600 hr to transmit the report, and then promptly went back to sleep for 2 hours before breakfast After that he was up for the whole day and only rarely took a nap

These two men, both petty officers trained rigidly in naval discipline, carried out identical duties on the expedition Whereas one's sleep was disrupted, the other showed no interference at all

These findings show that the conventional 8 hours may indeed represent a biological need, and is influenced neither by the absence of social pressures nor by the light darkness patterns Nor indeed is it influenced by physical work, although there are variations from day to day, the average hours of sleep during the month do not change

Summary and Conclusions

Members of the British North Greenland Expedition, living in the Arctic as a partially organised community, showed interesting disruption of their sleep/wakefulness patterns

The time of going to sleep and of getting up varied greatly, especially during midwinter (continuous darkness) and midsummer (continuous light), and without special preference to a particular hour

During the continuous darkness and continuous light more of the 24 clock hours were used for sleep, though the monthly total variations over the 2 years were slight, there were no great differences between months of out door activity and months when the men were confined to the hut The winter months were characterised by many interruptions of sleep, and by the taking of naps There was, however, no relationship or coincidence between interrupted sleep and naps

The effects of specific routine duties on sleep showed how men varied when there was no need to conform to a social pattern This varied response was seen in men whose backgrounds of Service discipline and training were identical

Though the men were at liberty to sleep almost as long as they liked, the mean duration of sleep was 7 9 hours The approximate period of 8 hours taken in temperate climates would indeed appear to represent a normal demand

We wish to thank Mr Roger Matchett and Petty Officer *D E Lee for valuable technical assistance*

PHYSICIAN

MEDICAL DEPARTMENT E, FREDERIKSBERG HOSPITAL, COPENHAGEN, DENMARK

SINCE purified preparations of vitamin B_{12} became available in 1949, combinations of the pure vitamin + "intrinsic factor" have been widely used in the oral treatment of pernicious anæmia Their adequacy over long periods is, however, somewhat in doubt, and oral versus parenteral treatment of pernicious anæmia has been discussed (Berlin 1953, Mollin and Ross 1953, 1954, Spies et al 1953, Gerhartz and Koelle 1954 Heinrich 1954, Lowther et al 1954, Baker and Mollin 1955, Blackburn et al 1955, Begemann 1957, Ungley 1957)

Since low levels of vitamin B_{12} in the serum or in the plasma may precede clinical signs of vitamin-B_{12} deficiency in pernicious anæmia (Mollin and Ross 1954, Østergaard Kristensen and Søeborg Ohlsen 1956), determination of the vitamin B_{12} level in the plasma is likely to afford not only a specific but also the earliest method of disclosing whether pernicious anæmia therapy is insufficient To elucidate this problem we followed the vitamin-B_{12} levels in the plasma and the hæmatological values in twelve patients According to the ordinary principles of maintenance therapy prevailing in the department, they were treated by the oral preparation 'Cycoplex MCO,' which consists of vitamin B_{12} plus small quantities of hog pyloric mucosa (see below)

Material

The material comprises twelve patients from the Frederiksberg Hospital, medical department E ten women age 45–84 and two men aged 65 and 75 All presented typical pernicious anæmia megaloblastic bone-marrow, abnormally low vitamin B_{12} levels in the plasma, histamine refractory achlorhydria, anæmia, and normal absorption of fat

Before treatment the vitamin-B_{12} levels in the plasma averaged 57 μμg per ml (range 10–120 μμg per ml), the lower limit of normal being 150 μμg per ml (see below) The hæmoglobin (Hb) level averaged 49% (range 34–77%), the red cells 1,740,000 per c mm (range 1,130,000–2,890,000 per c mm)

Methods

The vitamin B_{12} levels in the plasma were determined (by H P Ø K) by the method using *Lactobacillus leichmannii* 313 (Østergaard Kristensen 1956) Normal values for adults are on an average 392 μμg per ml (range 150–950)

Sternal bone marrow was examined (by A S O) partly in sections after coagulation and mounting and partly in smears stained by the method of May Grünwald Giemsa

Other hæmatological studies—Hb level (100% = 14 8 g per 100 ml), red-cell counts, colour index $\left(\frac{\text{Hb \%}}{\text{erythrocytes (mill)} \times 21}\right)$, total and differential white-cell counts, and serum-iron determinations (by the method of Hoyer 1950)—were made by the Central Laboratory of the Frederiksberg Hospital.

The patients were admitted while the treatment was being instituted and then discharged for frequent out-patient control. The control period was 7–25 months on maintenance therapy. In most cases the vitamin-B_{12} levels in the plasma were determined at intervals of 1 or 2 months.

Initial Treatment

At the outset ten of the twelve patients had intramuscular injections of vitamin B_{12}, usually 30–60 μg daily for the first 10 days. In a few cases this treatment was then supplemented by weekly injections of 60 or 90 μg, in one up to 300 μg, of vitamin B_{12}. The total dose of vitamin B_{12} administered parenterally ranged from 300 to 1080 μg and was given over a period of from 10 to 51 days. In case 11 the treatment was instituted with 'Hepsol fortior MCO' (see below) 5 ml four times in the course of 20 days, and in case 1 cycoplex was given from the outset. A possible deficiency of other hæmatopoietic substances, primarily iron and ascorbic acid, was met by adequate measures (cf Pedersen et al 1957).

All the patients gave a satisfactory initial response—i e, a typical reticulocyte reaction and a satisfactory increase in erythrocyte-count.

Maintenance Therapy

After this initial therapy nine of the ten patients who had had injections of vitamin B_{12} were started on treatment with cycoplex MCO. The group with cycoplex as maintenance therapy thus comprised ten patients (cases 1, 2, 3, 4, 4a, 5, 7, 8, 9, and 10).

Case 12a, who initially had injections of vitamin B_{12}, was shifted to injections of hepsol fortior MCO, and in case 11 the treatment with hepsol fortior was just continued.

Preparation and Dosage

Cycoplex MCO.—Each capsule contains 5 μg of crystalline vitamin B_{12} + intrinsic factor corresponding to 50 mg of dried hog pyloric mucosa suspended in oil. The daily maintenance dose was two to four capsules daily; it was increased later in two cases to eight capsules daily.

Hepsol fortior MCO.—This contains liver extract corresponding to 10 "clinical units" plus 20 μg of crystalline vitamin B_{12} per ml. The maintenance dose for the two patients who served as "controls" of those treated with cycoplex was 5 ml of intramuscular hepsol fortior every 2 or 3 weeks.

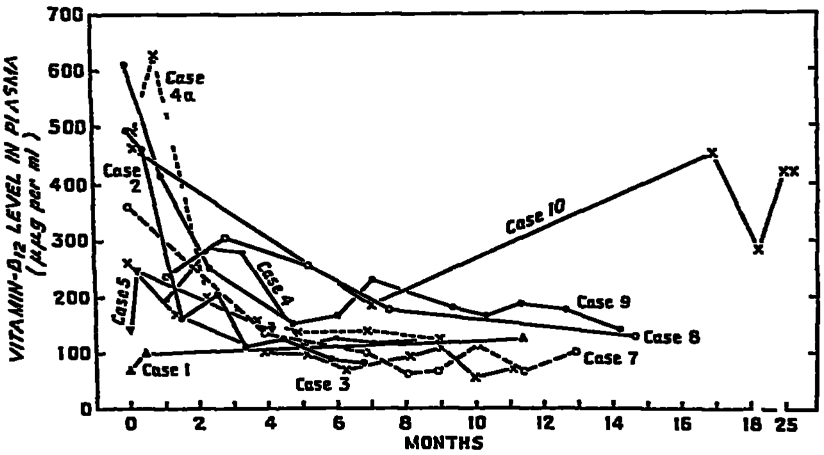

Fig 1—Vitamin B_{12} levels in plasma in 10 patients with pernicious anæmia on oral maintenance therapy with cycoplex MCO (vitamin B_{12} + hog pyloric mucosa). All but case 1 had initially received injections of crystalline vitamin B_{12} amounting to a total of 300—1080 μg, which had raised the vitamin B_{12} levels in plasma to normal.

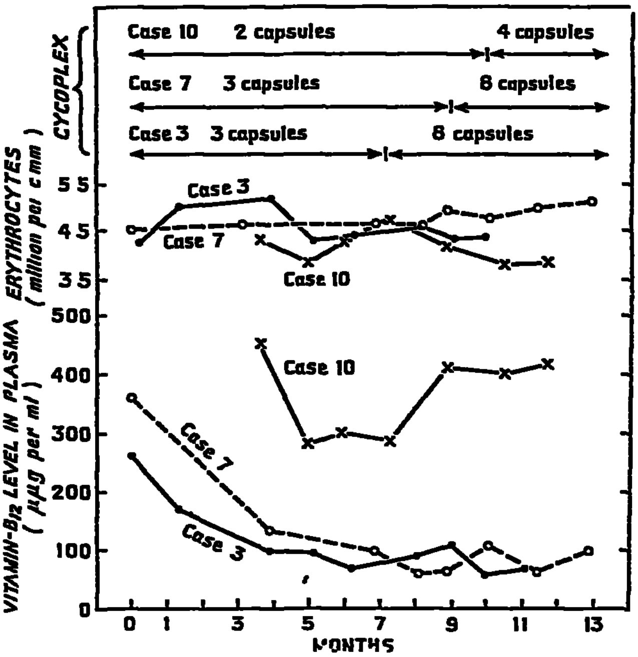

Fig 2—Vitamin B_{12} levels in plasma and erythrocyte-counts in 3 patients with pernicious anæmia on treatment with cycoplex MCO. After cases 3 and 7 had been treated for 7 and 9 months respectively, daily dose was increased from 3 to 8 capsules.

Results

Vitamin-B_{12} Levels in Plasma during Oral Maintenance Therapy with Cycoplex

Fig 1 shows the vitamin-B_{12} levels in the plasma during treatment with cycoplex. Case 1 (lowest curve on the left) did not have injections but was started at once on cycoplex. After a year's treatment his vitamin-B_{12} level in the plasma was only 125 μμg per ml.

In eight of the nine patients whose treatment began with injections of vitamin B_{12} the vitamin-B_{12} levels in the plasma had been raised to normal when cycoplex was started. In case 5 the vitamin-B_{12} level at that time was only 140 μμg per ml, but the first determination after cycoplex was started showed a value above 200 μμg per ml in this case too.

After 99–154 days—i e, after 3–5 months' maintenance therapy with cycoplex—the vitamin-B_{12} levels in the plasma had fallen, however, to abnormally low values—less than 150 μμg per ml in six of the nine patients. In six of them, who remained under control, this level remained unchanged or declined further.

Cases 8 and 9 showed for some time subnormal levels which, however, after 14–15 months fell below 150—140 and 130 μμg per ml respectively.

Only case 10 had an entirely normal level of vitamin B_{12} in the plasma after more than 2 years on cycoplex. Her initial level had been 50 μμg per ml—i e, decidedly in the range of pernicious anæmia, as in the other patients.

Dependence of Vitamin-B_{12} Level on Intensity of Initial Treatment

It might be presumed that the more intensive the initial treatment the longer is the period, during

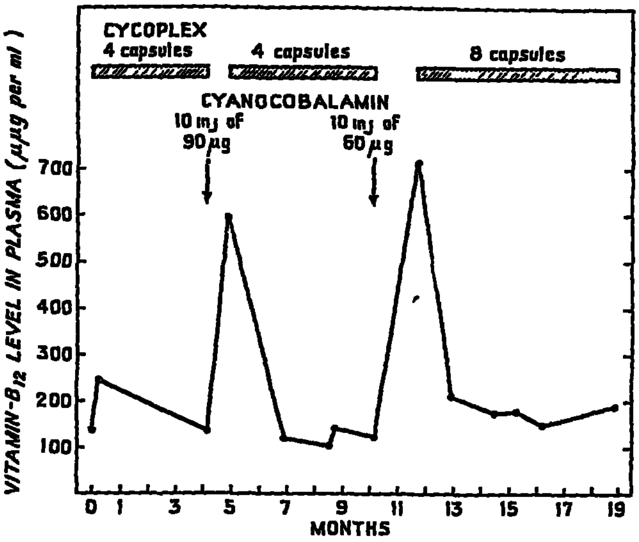

Fig 3—Case 5 vitamin B_{12} levels in plasma in pernicious anæmia treated with cycoplex MCO and intermittent injections of crystalline vitamin B_{1}

insufficient maintenance therapy, before the vitamin B_{12} level in the plasma falls to abnormally low values This question cannot be answered by the present study, but cases 4 and 4a, who had the most intensive initial treatment (1050 and 1080 μg of vitamin B_{12} respectively), showed levels lower than 150 μμg at the end of 5 months, whereas the patient who exhibited a normal level at the end of 2 years (case 10) had only received 540 μg of vitamin B_{12} initially

Dependence of Vitamin-B_{12} Level on Dose of Cycoplex

Case 10, whose vitamin-B_{12} level remained normal throughout 2 years on cycoplex, received two capsules daily during the first 10 months, and after that four capsules daily The two other patients (cases 8 and 9) whose vitamin-B_{12} levels also remained higher for some time than in the other patients, also had four capsules daily Their maintenance dose did not, however, differ from that in some of the patients whose vitamin-B_{12} levels soon fell to a low value

In two patients (cases 3 and 7) whose vitamin-B_{12} levels in the plasma were always low the dose of cycoplex was increased from three to eight capsules daily Fig 2 shows that, even after 4 months on this increased dose, the level of vitamin B_{12} in the plasma remained abnormally low—70 and 100 μμg per ml respectively The increase in the dosage did not raise the vitamin-B_{12} level

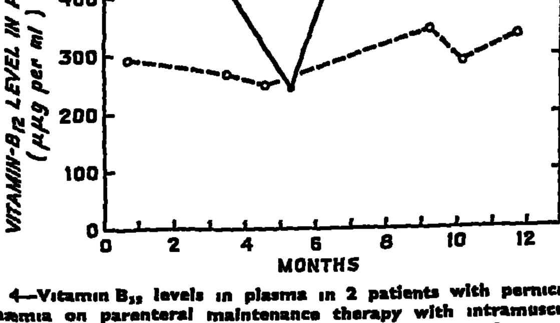

Fig 4—Vitamin B_{12} levels in plasma in 2 patients with pernicious anæmia on parenteral maintenance therapy with intramuscular injections of liver extract (hepsol fortior MCO) 5 ml about every 2 weeks Vitamin B_{12} levels were determined at least one week, and usually two weeks, after injections

Fig 3 illustrates the findings in case 3 Owing to a low vitamin B_{12} level in the plasma and the occurrence of paræsthesiæ during cycoplex therapy, this patient had injections of crystalline vitamin B_{12} in two periods, this led to a prompt rise in the vitamin-B_{12} level to normal and improvement of the paræsthesiæ

Vitamin B_{12} Level in Plasma during Maintenance Therapy with Injections of Hepsol Fortior

Fig 4 shows the vitamin-B_{12} levels in the plasma of the two patients (cases 11 and 12a) treated with injections of hepsol fortior At the end of 9–10 months both had vitamin-B_{12} levels within the normal range The estimations were made at least 1 week, and usually 2 weeks, after the last injection of hepsol

Vitamin B_{12} Level in Relation to Hæmatological Findings during Oral Maintenance Therapy

Table I gives these hæmatological findings in nine patients on cycoplex when the vitamin-B_{12} level in the plasma was first found to be less than 150 μμg per ml These patients had initially received injections of vitamin B_{12}

In six of these nine patients the vitamin B_{12} levels in the plasma continued to be estimated after the levels had fallen to less than 150 μμg per ml Table II compares the hæmatological values at the time shown in table I with those found after the vitamin B_{12} levels had remained low for a long time in these six cases

The tables show (1) that a vitamin-B_{12} level of less than 150 μμg per ml was found in the plasma when the *Hb* was entirely normal and the number of red cells satisfactory (averaging about 4,500,000 per c mm and being less than 4,000,000 per c mm in only one case), (2) that a low vitamin B_{12} level in the plasma for an average of $5^1/_2$ months did not involve a decrease of either Hb or red cells One patient with a low vitamin B_{12} level in the plasma was followed up for nine months without any signs of recurrence of the anæmia

TABLE I—VITAMIN B_{12} LEVEL IN PLASMA, HB, RED CELLS, AND COLOUR-INDEX DURING MAINTENANCE THERAPY WITH CYCOPLEX WHEN VITAMIN B_{12} LEVEL WAS FIRST FOUND TO BE LESS THAN 150 μμG PER ML

Average of 9 patients

Vitamin B_{12} level in plasma (μμg per ml)	Hb (%)	Red cells (million per c mm)	Colour index
126 (range 110–145)	91 (range 80–104)	4 29 (range 3 57–5 18)	1 01 (range 0 93–1 17)

Fig 2 shows the vitamin-B_{12} levels in the plasma and the number of red cells for three of the patients (cases 3, 7, and 10) on cycoplex In case 7 the number of red cells was normal despite an abnormally low level of vitamin B_{12} in the plasma In case 10 the number of red cells was on several occasions less than 4,000,000 per c mm despite a normal level of vitamin B_{12} in the plasma This combination of a low vitamin B_{12} level and a normal number of red cells in one patient and of a normal vitamin B_{12} level with a low number of red cells in another emphasises the fact that the number of red cells is not an ideal indicator of a possible vitamin B_{12} deficiency

Vitamin B_{12} Level in Plasma in relation to Erythropoiesis

In seven of the ten patients on cycoplex and in one of those on hepsol sternal puncture was repeated during the treatment The bone marrow could be described as *completely normal* in only two of them the one who had a normal level of vitamin B_{12} in the plasma after more than 2 years on cycoplex (case 10), and the one who was treated with hepsol (case 12a) and also had a normal level of vitamin B_{12} in the plasma

Of the remaining six patients on cycoplex in whom sternal puncture was repeated (cases 2, 3, 4, 4a, 5, and 7)

TABLE II—VITAMIN-B_{12} LEVELS IN PLASMA, HB RED CELLS, AND COLOUR-INDEX DURING MAINTENANCE THERAPY WITH CYCOPLEX *a* WHEN VITAMIN-B_{12} LEVEL OF LESS THAN 150 µµG PER ML. WAS FIRST FOUND, *b* AFTER AN AVERAGE OF 162 (RANGE 97–270) DAYS WITH VITAMIN-B_{12} LEVELS OF LESS THAN 150 µµG PER ML.

Average of 6 patients

Vitamin-B_{12} level in plasma (µµg per ml)		Hb (%)		Red cells (mill per c mm)		Colour index	
a	*b*	*a*	*b*	*a*	*b*	*a*	*b*
120 (range 110–145)	95 (range 55–120)	94 (range 89–104)	94 (range 85–105)	4.56 (range 4.13–5.18)	4.53 (range 4.17–5.14)	0.98 (range 0.93–1.02)	0.97 (range 0.91–1.06)

four (cases 2, 3, 5, and 7) showed a few typical (Ehrlich) megaloblasts despite a normal amount of Hb and a normal erythrocyte-count 3–6 months after an abnormally low level of vitamin B_{12} had first been found. The two others (cases 4 and 4a) had no characteristic megaloblasts but one of them had "macrometamyelocytes."

Neurological Signs

Before the treatment four patients (cases 4, 4a, 10 and 11) had shown slight signs of myelopathy, which disappeared or subsided perceptibly during the initial treatment.

In case 4, who had lost the Achilles-tendon reflexes before treatment, these reflexes became normal when the vitamin-B_{12} level in the plasma had been abnormally low for several months. Two patients (cases 1 and 5) with no pre-treatment signs of myelopathy, complained during cycoplex therapy of paræsthesiæ. At that juncture the peripheral blood was normal, whereas the vitamin-B_{12} level in the plasma was low. After injections of vitamin B_{12} the paræsthesiæ disappeared in case 1 and improved in case 5.

Discussion

At our present stage of knowledge, and with our present diagnostic methods the maintenance therapy of pernicious anæmia must keep normal the amount of Hb, the number of red cells the bone-marrow and the vitamin-B_{12} level in the plasma. Our results show that the oral administration of cycoplex MCO, which consists of vitamin B_{12} and small quantities of hog pyloric mucosa, did not keep the bone marrow and the vitamin-B_{12} level normal: in nine of ten patients the vitamin-B_{12} level in the plasma was abnormally low, in four of seven patients the bone-marrow was "partially megaloblastic", and in a fifth case "pernicious-anæmia neutrophils" were found. This maintenance therapy is therefore insufficient, although the amount of Hb and the erythrocyte-counts were normal.

The doses of vitamin B_{12} injected initially were probably not sufficient to restore tissue reserves in our patients (see below), but even in the two patients who received more than 1000 µg of vitamin B_{12} initially the vitamin-B_{12} level in the plasma fell to below normal within 5 months on cycoplex.

Our investigations confirmed that patients on maintenance therapy for pernicious anæmia can have a low vitamin-B_{12} level in the plasma for months without showing clinical signs of vitamin-B_{12} deficiency. Determinations of the vitamin B_{12} level in either the plasma or the serum are therefore necessary for assessing the efficacy of maintenance therapy.

Since the various combined preparations for oral treatment of pernicious anæmia differ in composition and in degree of purification of the intrinsic factor, the experience with one preparation (cycoplex MCO) does not permit conclusions regarding the efficacy of others. Whether any of the commercial preparations for oral use can maintain normal vitamin B_{12} levels in the plasma in long-term therapy is a question which calls for further study. The failure of a threefold dose of our preparation to raise the vitamin-B_{12} level suggests that simple underdosage of intrinsic factor is not the whole explanation.

In discussing oral versus parenteral treatment of pernicious anæmia it is important to realise, as Mollin and Ross (1953) and Ungley (1957) point out, that the quantities of vitamin B_{12} required to afford "satisfactory" increases in reticulocyte and erythrocyte counts in anæmic patients constitute only a very small fraction of the quantities required to restore normal tissue reserves of vitamin B_{12}. Since in untreated pernicious anæmia the deficit in liver-tissue reserves presumably amounts to about 1500 µg of vitamin B_{12} (cf. Ross and Mollin 1957, Swendseid et al. 1957) and since studies of vitamin B_{12} labelled with radioactive cobalt (Glass et al. 1954, Baker and Mollin 1955, Callender and Evans 1955) have proved that the amount of vitamin B_{12} which can be absorbed from the intestinal tract is very limited (1–2 µg after the administration of 50 µg of vitamin B_{12} + intrinsic factor) the depleted reserves can certainly not be replaced within a short time by the usual oral treatment.

In patients with a low level of vitamin B_{12} in the plasma indicating small or depleted tissue reserves the risk of hæmatological relapse or of the development of neurological deficiency signs must be high. This applies particularly under conditions in which either the requirement is increased (infection, hæmorrhage, &c.) or the absorption is decreased. In treating pernicious anæmia, therefore, one must try not only to increase the Hb and the red cells to normal but also to replace the depleted tissue reserves.

The initial treatment should therefore be by the parenteral route. In view of the considerable vitamin-B_{12} deficiency in the tissue reserves of these patients this initial treatment must also be much more intense than that in current use. Most patients will probably require about twenty injections of 100 µg of vitamin B_{12}, if normal tissue reserves are to be restored.

Maintenance therapy.—If oral therapy is chosen, it seems absolutely necessary to control the state by determinations of the vitamin-B_{12} level in the plasma and by the appearance of the bone-marrow. In the absence of facilities for determining the vitamin-B_{12} level in the plasma it seems wise at present to use parenteral treatment also for maintenance purposes. The cheapest form is injections of vitamin B_{12}—e.g., 100 µg every two weeks. Using this procedure the physician knows that he can maintain not only normal erythrocyte-counts but also normal vitamin-B_{12} levels in the blood.

Summary

Ten patients with pernicious anæmia were treated initially with injections of vitamin B_{12} (cyanocobalamin), which brought the vitamin-B_{12} level in the plasma up to a normal value. Nine of these patients were given oral maintenance therapy with 'Cycoplex MCO,' which consists of vitamin B_{12} and small quantities of dried hog pyloric mucosa. During this treatment the levels of vitamin B_{12} in the plasma fell to abnormally low values in eight of the nine patients, and in one patient,

who also had received cycoplex as initial therapy, the level remained low At the same time the bone-marrow showed signs of insufficient therapy, whereas the amount of Hb and the erythrocyte-count mostly remained normal

It proved impossible to restore the vitamin B_{12} in the plasma to a normal value by increasing the dose of cycoplex, but the injection of vitamin B_{12} immediately did so

In two patients treated with intermittent injections of a preparation of liver extract supplemented with crystalline vitamin B_{12} ('Hepsol fortior MCO') the level of vitamin B_{12} remained normal

The control of maintenance therapy of pernicious anæmia should include, in addition to determination of Hb and erythrocyte count, determination of the vitamin-B_{12} level in the plasma and examination of the bone marrow Only in this way can insufficiency of the therapy be disclosed at an early stage

As initial treatment of pernicious anæmia, injections of vitamin B_{12} are recommended, and this initial treatment should be more intensive than usual, the total dose being about 2000 µg of vitamin B_{12}

The oral preparation cycoplex MCO, which consists of vitamin B_{12} and small quantities of hog pyloric mucosa, appears to be insufficient, because it does not keep the bone-marrow and the vitamin-B_{12} level in the plasma normal

The efficacy of other oral preparations should be studied by determining the vitamin-B_{12} level in the plasma and by examining the bone-marrow

" The present generation of consultants have never been general practitioners They have planned their own careers and applied their own labels Further, most of them have found that the way to success has been through increasing limitation They are one tool technicians or one disease diagnosticians On the whole they have had a simpler training and they lead an easier life than the general practitioners, and they often have less ability and certainly less wisdom The practitioner needs a consultant for advice about a particular problem in a particular patient He chooses the consultant either for his well known familiarity with that particular problem, or for his probable ability to handle, and to impress, that particular patient The choice of a consultant is one of the most important decisions of general practice There is, unfortunately, a tendency today for patients to choose their own consultants, usually on the advice of an acquaintance at a cocktail party, the doorkeeper at the hotel, or the gossip writer in an evening paper "—Sir HENEAGE OGILVIE in *Medical Ethics*, edited by Dr Maurice Davidson London, 1957, p 65

SERUM-LIPIDS AND ATHEROSCLEROSIS AMONG YEMENITE IMMIGRANTS IN ISRAEL

Israel's population is composed of immigrants from East and West differing widely in their cultural background and ways of life Each group is reluctant to change its habits of eating, so that in Israel there is a unique opportunity for a long-term experiment on the influence of diet upon serum cholesterol levels and the incidence of atherosclerosis

Apart from the higher atherosclerosis mortality rate in Israel among immigrants from Western countries (Dreyfuss 1953, Toor et al 1954), a striking difference has been found between Yemenites who had immigrated over twenty years ago ("early" Yemenite immigrants) and those who had immigrated within the previous five years ("recent" Yemenite immigrants) After assembling statistical data on atherosclerosis mortality rates among different communities in Israel during the years 1953–55, we studied 528 recent and early Yemenites to determine their social conditions, diet, nutritional status and serum levels of cholesterol, phospholipids, and total lipids We then tried to correlate the findings with the atherosclerosis mortality rate

All the Yemenites were examined by one of us (J A) with the help of their local physician Those with a history of cardiovascular disease or other abnormality liable to affect the serum cholesterol level were excluded from the inquiry, and so were those with a blood pressure higher than 140/90 mm Hg, those who were very underweight, those with enlarged spleen or liver, and those with low blood cholesterol levels in the presence of impaired liver-function tests Pregnant and lactating women were also excluded The sex and age distribution of the 274 recent and 254 early Yemenites selected are shown in table I

TABLE I—AGE AND SEX DISTRIBUTION OF RECENT AND EARLY YEMENITES

Age (years)	Recent Yemenites		Early Yemenites	
	Male	Female	Male	Female
35–44	52	42	43	47
45–54	57	43	48	51
54–64	56	24	37	25
Total	165	109	128	126

Social Conditions

Data about social status were collected with the help of the local physician and social worker and are set out

TABLE II—OCCUPATIONS OF RECENT AND EARLY YEMENITES

Age and sex		Yemenite immigrants	No of cases	Farm workers (%)	Industrial workers (%)	White collar workers small artisans, pedlars (%)	Housewives (%)	Dependent on social relief (%)	Other dependants (%)
Males	35–44	Recent	52	80·8	9·6	5·8		3·8	
	45–54		57	45·6	3·5	12·3		38·6	
	55–64		56	21·4	5·4	8·9		64·3	
	35–44	Early	43	62·7	30·3	7·0			
	45–54		48	62·5	20·9	10·4			6·2
	55–64		37	54·1	16·2	10·8			18·9
Females	35–44	Recent	42	26·2			73·8		
	45–54		43	18·6			81·4		
	55–64		24	8·3			41·7	50·0	
	35–44	Early	47	31·9	4·3		63·8		
	45–54		54	24·1			75·9		
	55–64		25				76·0		24·0

in table II The recent immigrants were living in transit camps under poor conditions, whereas most of the early immigrants lived in their own houses under better economic circumstances The number of children was highest and monthly income lowest among recent Yemenites Among the recent immigrants the mean number of persons per family was 6·5, compared with 5·0 in the early Yemenites (Yemenite children leave their families to fend for themselves at an early age and only children dependent on the support of their families are included in these figures) The mean monthly income per person in the recent Yemenites was I L 19 (I L 1·80 = $1), compared with 38 I L in the early immigrants

Dietary Survey

The survey was conducted during the clinical and laboratory investigation and includes additional data, collected by the social worker, on the nutritional habits and consumption and composition of food of 55 recent and 21 early Yemenite families The figures in table III represent average daily values

The diet of recent Yemenites contains a lot of *pita*, a type of flat yeastless bread They also eat large quantities of vegetables, very little meat (once weekly), and very little fat (table III), which is mainly in the form of *samne** (boiled butter with *hilbe*, the seed of fenugreek (*Trigonella fœnumgræcum* L)) As the quantity of ingested fat is very small, the nature, composition (Bronte-Stewart et al 1956), and/or preparation (Sinclair 1956) of this fat probably has little influence on the pathogenesis of atherosclerosis † Both early and recent Yemenites make abundant use of sunflower seeds, chick-pea seeds, nuts, and almonds

Though the data collected on recent and early Yemenites express long-term nutritional habits, they cannot be as accurate, of course, as those provided by a controlled nutritional experiment Our results are, however, closely similar to those obtained by Strauss et al (1954) (table III)

Among males, 94% of recent and 92% of early Yemenites consumed more than a litre of alcohol monthly There was no striking difference in tobacco consumption between the two groups

Clinical and Laboratory Findings

Height and Weight

There was no significant difference in the average height of the two groups, but the weight of the recent Yemenite immigrants was significantly lower The weight/height ratio ‡ (table IV) was thus lowest in recent Yemenites In the 35–44 age group the weight/height ratio was normal among early Yemenites and fell with increasing age In recent Yemenite women the ratio was rather higher than in men of the same age and did not drop with increasing age

TABLE III—DAILY DIET OF YEMENITES

Group	Total calories per day	Animal proteins (g)	Fats (g)	% calories derived from fats
Recent Yemenites	1750	12	30	16
Early Yemenites	2350	20	55	21

---

* *Samne* is prepared by boiling ordinary butter, which contains about 82% fats, with small amounts of *hilbe* for its flavour The water thus extracted is discarded, so that the new product contains about 95–98% fats As the cooking of the butter is not performed under pressure, it is doubtful if all fatty acids undergo complete oxidation

† During the period of rationing, when the government supplied fats and animal proteins cheaply and equally to the whole population, the recent Yemenite immigrants were accustomed to selling their rations and restricted themselves essentially to food rich in carbohydrates

Figures in bold type show highly significant differences (critical ratio > 3·5)
Those in italics show significant differences (critical ratio > 2·5)

ite immigrants were significantly higher As those with high blood-pressure were not included in this study, no definite conclusions on "coronariness" (Gofman et al 1954) could be drawn from these figures

Blood

Blood samples were collected in the morning from fasting subjects and separated three to four hours later Every blood examination was performed in duplicate, and results diverging by more than 5% were discarded Our method was described in an earlier communication (Toor et al 1954)

Hæmoglobin—The mean hæmoglobin values (determined with Sahli's apparatus) were slightly lower in both groups than the accepted values in Western countries (Berry et al 1952) In females these values were lower than in men for all groups In men the hæmoglobin values dropped with increasing age, but not so in women The hæmoglobin values of early Yemenite immigrants were significantly higher than in recent Yemenite groups The gap between the two decreased with increasing age There was no significant difference in hæmoglobin values of early and recent female Yemenite immigrants

Cholesterol—The mean and median serum cholesterol value was lowest for recent Yemenites in both sexes and in all age groups (table IV, fig 1), and the difference was statistically significant (males, t=7 35–5 15–6 30, females, t=3 71–6 35–4 21)

Phospholipids—The values were higher among females in all age-groups

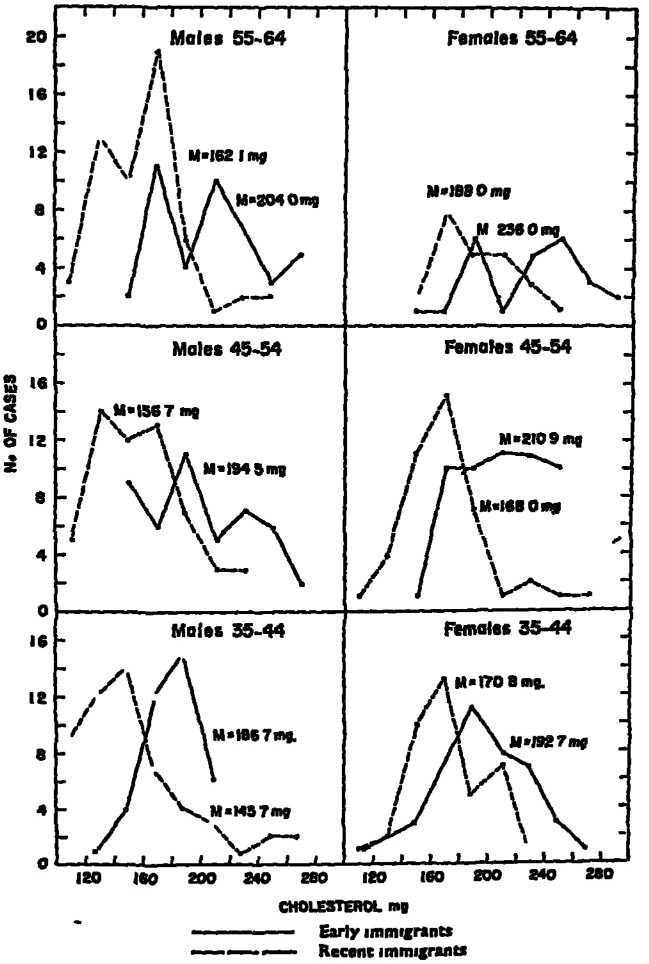

Fig 1—Distribution of serum-cholesterol values in early and recent Yemenite immigrants in Israel M = median value

TABLE V—ATHEROSCLEROSIS MORTALITY OF EARLY AND RECENT YEMENITES (1953–55) (RATES PER 1000 INHABITANTS PER YEAR)

Age and sex		General population		Yemenite immigrants			
				Early		Recent	
		No of deaths	Mortality rate	No of deaths	Mortality rate	No of deaths	Mortality rate
Males	35–44	47	0 44				
	45–54	203	2 26	6	3 3	2	0 49
	55–64	393	8 56				
	65 +	945	32 2	15	23 6	8	6 3
Females	35–44	20	0 19	1	1 8		
	45–54	82	1 04	3	1 8	2	0 51
	55–64	262	5 9				
	65 +	932	26 5	12	20 0	6	4 7

Cholesterol/phospholipid ratio—This ratio remained within normal limits, but was lowest among recent Yemenites

Total lipids—The mean values were lowest among recent Yemenites, and the differences were significant in both sexes

The mean of the results for each age group and the standard deviation are set out in table IV

Mortality from Atherosclerosis

To minimise the errors due to detailed clinical diagnosis, we have used the group diagnosis of "atherosclerosis" in which we did not include deaths due to hypertension or heart failure induced by causes other than atherosclerosis Most of the death certificates from which mortality figures were derived were based on clinical rather than on post mortem examination But our main object was a *comparative* study of atherosclerosis mortality-rates in the different communities in Israel As most of the Jewish population in Israel get their medical treatment through the Sick Fund of the General Federation of Labour, the proportion of errors due to death certificates based on clinical diagnosis is likely to be the same in all sections of the community

The atherosclerosis mortality-rate in 1953–55 was about four times higher among early Yemenite immigrants than among recent ones (table V) In fig 2 the rates are compared with those for European Jews (Toor, Katchalsky, Agmon, and Allalouf) It should be stressed that the body build of Yemenites, both early and recent, remained the same Both groups obeyed religious laws and conformed to social customs to the same extent Their ways of life were practically unchanged, and no mental stress could be incriminated in the early Yemenites The mortality rate from infectious diseases was similar in both groups The mortality-rate from malignant tumours was lowest among the recent immigrants The mortality rate from all causes in recent Yemenites over 65 was practically the same as the over 65 rate among other national groups in Israel The lower mortality-rate from atherosclerosis among recent Yemenites cannot therefore be ascribed to death from other causes at a younger age

Discussion

Keys et al (1950, 1954) established a relation between the amount of fat in the diet, the serum cholesterol level, and the frequency of atherosclerosis Katz (1953) pointed out that the differences in the incidence and severity of atherosclerosis "tend to correlate with culturally conditioned variations in nutrition and diet rather than with racial, climatic or other factors" Most of the Yemenites we studied were manual workers or clerks of limited income, and the recent immigrants were the poorest Their nutritional status was lower

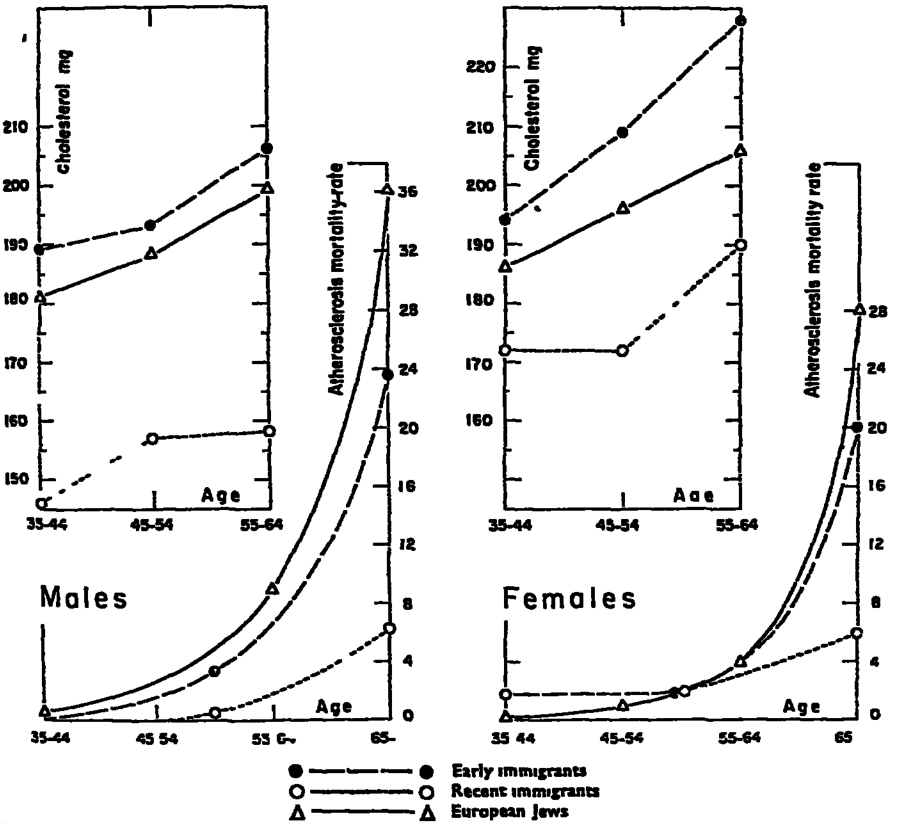

Fig 2—Atherosclerosis mortality and mean serum-cholesterol values in early and recent Yemenite immigrants in Israel

than that of the early immigrants, and their serum-cholesterol, phospholipid, and total-lipid values were also lower and were in accordance with the values reported in Guatemalan farm-workers (Mann et al 1955) and in South African Bantus (Bronte-Stewart et al 1955)

The lower mortality from atherosclerosis among Yemenites in Israel has attracted much interest during the past few years In a series of 967 post-mortem examinations, including 123 Yemenites, Shalom (1954) found a third coronary artery in 0 83% of European Jewish immigrants as against 2 44% in Yemenite immigrants—a possible explanation for the lower incidence of myocardial infarction in Yemenite Jews But this explanation is unlikely because of the increased atherosclerosis mortality among the early Yemenite immigrants

Our own observations indicate that varicose veins and thrombophlebitis are uncommon among Yemenite immigrant women, even in those who have had many pregnancies Berman-Yeshurun (1956) found that the incidence of atherosclerosis and thrombophlebitis was low among Eastern Jewish immigrants These findings raise the possibility that these people are less liable than others to intravascular clotting The rarity of thromboembolic phenomena among the Bantus (Keys 1956) and the Dutch East Indians (Van Unnik and Straub 1953), however, and the decrease of thromboembolism in Norway during the late war (Strom 1954), suggest a relation between low-fat diet, thrombosis, and atherosclerosis

It is also difficult to explain the low serum cholesterol values on the basis of a metabolic genetic factor in recent Yemenite arrivals, because, with increased consumption of food, particularly fats, cholesterol values and atherosclerosis mortality-rates approach those of Europeans The possible effect of sunflower seed oil on serum-cholesterol levels does not seem to be relevant, since both groups eat sunflower seeds

The cholesterol levels in both early and recent Yemenite women aged 45–64 were significantly higher than in men of the same age We can suggest no satisfactory explanation for this interesting finding and we are investigating it further

The differences in the incidence of atherosclerosis among early and recent Yemenite Jewish immigrants can best be explained by the differences in total food intake determined by differences in income Furthermore, the recent Yemenite immigrants work harder, and remain in a state of caloric imbalance at the age when atherosclerosis is commonest

Summary

The nutritional status, serum-cholesterol values, and incidence of atherosclerosis were investigated in recent (within past five years) and early (over twenty years ago) Yemenite immigrants in Israel Serum-cholesterol and total lipid levels were significantly less in recent immigrants On the other hand, the atherosclerosis mortality-rate was four times higher, for the same age and sex, in the early Yemenite immigrants and approached the rate for European Jews Among the early immigrants, the average income per head was double that on which the later arrivals were living

This study, undertaken as a part of the research programme on morbidity and mortality from atherosclerosis among the various communities in Israel, has been made possible by a grant from the Kupath Holim, Workers' Sick Fund of Israel We wish to thank Dr G Kalner, chief of the statistical department, Israel Ministry of Health, for providing the data on mortality rates of different age groups, and we gratefully acknowledge the aid of Mrs S Seligson, head of the medical statistical department of the Sick Fund, for the statistical analyses

VENTRICULO-SUBDURAL DRAINAGE IN INFANTILE HYDROCEPHALUS

ANALYSIS OF EARLY RESULTS

D M FORREST

CONSULTANT SURGEON, THE HOSPITAL FOR SICK CHILDREN, AND THE WESTMINSTER CHILDREN'S HOSPITAL

MANY operations may relieve hydrocephalus, but none is suitable for all types of the disease In an attempt to fill this gap, the present procedure was devised by one of us (D M F) as a drainage from a lateral ventricle to the supratentorial subarachnoid space A brief announcement in these terms was made (Forrest 1955), but it became obvious soon afterwards that the method was in fact a ventriculo subdural drainage—a method which has been used before with different materials (Taylor 1909)

Thus founded in error, the operation would have been abandoned had we not observed that in a high proportion of the early cases the disease was becoming arrested This led us to persist with a longer trial The patients operated on in this series have now been followed up for between twenty and thirty-two months, and the effect of the operation can be seen in reasonable perspective

Material

To give the method a comprehensive trial, it was decided to perform the operation in all cases of progressive hydrocephalus, even in those with an apparently hopeless prognosis The present series comprises all cases of hydrocephalus seen in one unit at the Westminster Children's Hospital and The Hospital for Sick Children, Great Ormond Street, between October, 1954, and August, 1955 During this time there were 70 new cases at all ages up to 6 years Of these, 20 appeared to be arresting spontaneously, so were not operated on Of the remaining children, 4 died before operation could be done, and in 10, though treatment was required, it was abandoned because of active infective ventriculitis (8) or very gross thinning of the cortex (2)

In the 36 cases coming to operation, blockages were demonstrated at all the common anatomical sites (table I), and were of varied ætiology Many patients were in an advanced stage of the disease

Investigations

Only those tests used in selecting cases for this operation or in assessing the results will be discussed here, though all the usual *investigations for hydrocephalus* have been carried out

Circumference of head.—This is the most useful gauge of progressive hydrocephalus in all cases which still have some elasticity of the skull It is estimated weekly, if possible by the same observer on each occasion

Ventricular pressure.—This is estimated with the child quiet (if necessary, sedated) but not anæsthetised, and under these conditions we have achieved consistent results It is less informative than measurement of circumference, but, taken in conjunction with this, it offers a satisfactory means of assessing improvement or deterioration in comparison with previous readings

Subdural fluid should be sought at the time of ventricular tap Its presence may be due, among other causes, to a *hæmatoma or a natural ventriculostomy*

Thickness of cortex.—is estimated during ventricular puncture and confirmed by air studies

Analysis of ventricular fluid.—Evidence of recent hæmorrhage or active infection are indications for delaying or abandoning the operation

Dye studies.—Estimations of urinary excretion of dye after ventricular or thecal injection are mainly used for localising the block (Laurence 1957) and are not essential in an operation where this is not important They have been used in a few cases to demonstrate improved excretion after a successful operation

Method

Design of Apparatus

Drainage is achieved by means of a plastic tube passed through the cerebral cortex from a lateral ventricle to the supratentorial subdural space On several occasions, where various forms of drainage from a ventricle to another part of the body had failed, it was observed that failure was usually due either to blockage of the *distal* end of the tube (the proximal end remaining patent), or to displacement of the *proximal* end from the ventricle Accordingly, the tube was made with a deeply grooved cover on the distal end and a self-retaining proximal end (fig 1)

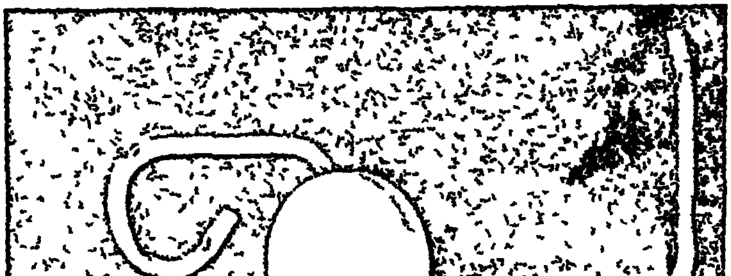

Fig 1—The Forrest disc with and without stylet in place

Plastics are the obvious materials to use, but there is some difficulty in choosing one with the required characteristics of flexibility, elasticity, and ease of moulding and of sterilisation Most important of all, the material must not produce a foreign-body reaction, or the tube will become blocked 'Polythene' has been widely used in similar procedures, and the first 11 operations were performed with discs of this material In those cases which failed, however, the discs were seen to be blocked by heavy deposits of fibrinous or collagenous material, and polythene was discarded in favour of nylon, a much more physiologically inert plastic All the remaining operations in this series were done with nylon discs, but more recently an even better material, polytetra fluoro ethylene, has become available This is almost completely chemically and

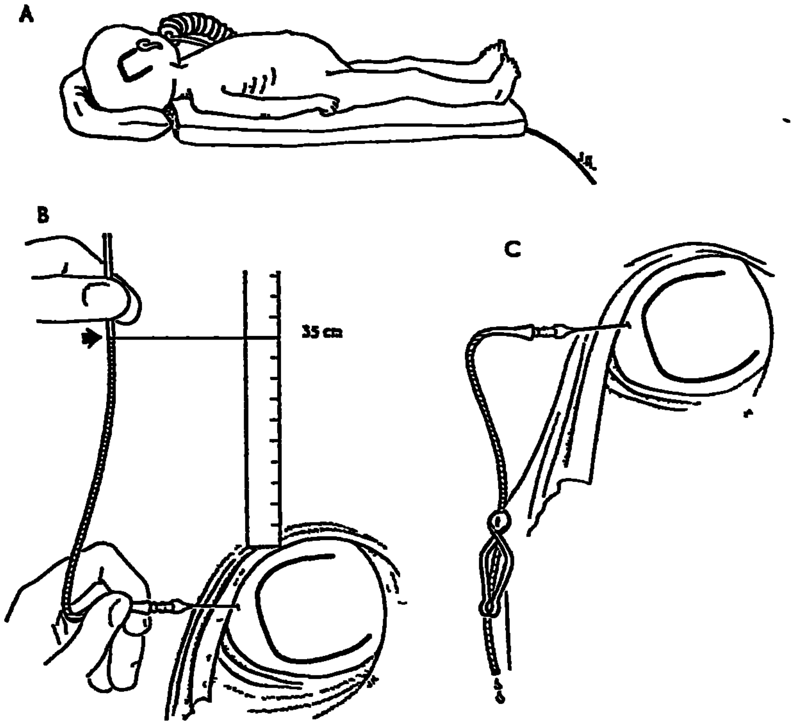

Fig 2—Stages of the operation as described in the text

physiologically inert, has a high softening temperature, and is unwettable The discs are now being manufactured of this plastic under the name of the 'Forrest Disc' *

With all these materials the method of construction has been the same The tube is shaped by passing a malleable wire through the lumen, bending to the required shape and then heating to the softening point of the plastic After cooling, the wire is withdrawn, whereupon the tube resumes the curved shape (This general method has wide applications in other surgical procedures where a tube of a certain curve or angle is required) The disc portion of the device is turned up from solid plastic rod

Operative Method

The actual insertion of the disc presents few difficulties it is straightforward (fig 2), and well tolerated by the patient Since the first 2 cases we have found it unnecessary to provide intravenous fluid or blood during operation

First, a short lumbar-puncture needle is inserted into the dependent lateral ventricle A half-metre length of polyvinyl chloride tubing of 2 mm bore is connected to it, and used as a manometer to measure the ventricular pressure (fig 2B) The tube is then lowered to drain the ventricles (fig 2C) While the dura remains intact, fluid is allowed to drip until the pressure falls to atmospheric, and this rapid decompression has been found not to disturb the patient

An osteoplastic flap is next reflected, usually in the right posterior parietal region (fig 2A) Sometimes the bone is thin enough to be cut with stout scissors but often it must be sawn in the usual manner The posterior limb of the bone section should be made about a centimetre anterior to the occipito-parietal suture If it is

---

* Manufactured by Crane Packing Ltd Slough, Bucks

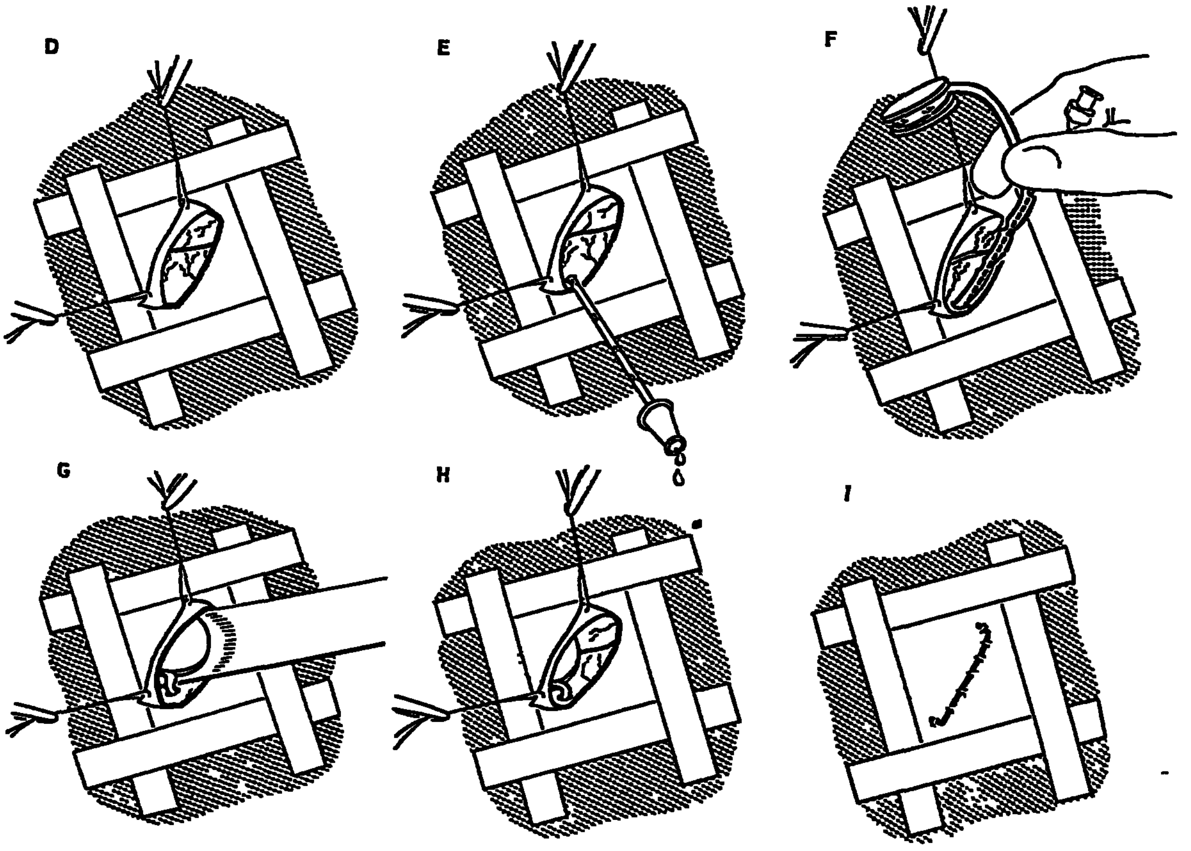

Fig 3—The operation continued and concluded

too close, the dura, which is adherent to the suture, may be inadvertently lacerated

The dura should not be opened until the ventricular pressure has fallen to a low level and the dura is seen to be indrawn If the skull is very thin this may not happen, because *the sutures override and the skull* collapses as fluid escapes In these cases it is helpful to elevate the parietal bone by means of a blunt hook placed under the bone edge

When the dura is incised the brain should fall away, leaving a space about 1 cm deep Thus the dural incision can be enlarged to 3 cm and the disc inserted without risk to the cortical vessels (fig 3D) When the brain has fallen away sufficiently, the lumbar-puncture needle may be withdrawn from the fontanelle

Selecting a bloodless area of the cortex near one end of the dural incision, the operator next passes a Jefferson's brain cannula into the lateral ventricle, to form a track for the insertion of the tube (fig 3E)

Before the device is inserted *it* is absolutely essential to make sure that there is no bleeding and to rinse away with Hartmann's solution all blood and clot which may have collected in the subdural space The *disc*, which has been sterilised by boiling or autoclaving, is next prepared by the insertion of a blunt ended hollow needle to straighten the tube, which is then passed down the track made through the cortex (fig 3F) When it enters the ventricle, fluid is aspirated and then reinjected as the stylet is withdrawn, thus ensuring that the tube is not blocked with clot or brain tissue The end of the tube then resumes its curled shape within the ventricle

TABLE I—DESCRIPTION OF THE 36 CASES COMING TO OPERATION

A Type	
Communicating	17
Non communicating	10
Unknown	9
Total	36

B Site of Block	
Aqueduct	5
4th ventricle foramen	2
Basal cistern	12
Arnold Chiari malformation	15
Unknown	2
Total	36

With the aid of a brain spatula (fig 3G), the disc is now rotated under the dural flap (fig 3H), well away from the operation site When hæmostasis is certainly complete, the dural flap is closed (fig 3I)

Postoperative Course and Complications

The postoperative course is usually smooth, though the temperature is often elevated for a few days The infant should be nursed flat for twenty-four hours, but supportive therapy is usually unnecessary The fontanelle does not often collapse in the dramatic way seen after some drainage operations As it is almost impossible to make a watertight closure of the dura, there is a risk of a collection of cerebrospinal fluid forming under the skin flap The risk is minimised by application of a firm dressing, but, if fluid does collect, it should be aspirated before it becomes infected

TABLE II—OPERATION RESULTS

—		No of cases	%
Operation successful (arrest immediately after operation)		13	36
Operation not successful		23	64
Arrested subsequently	5		
Still progressive	1		
Dead	17		
Total		36	100

TABLE III—FATE OF THE WHOLE SERIES

—	Arrested	Progressive	Dead
Operation	18	1	17
No operation			
Natural arrest	18		2
Persistent (i e , infection)		1	7
Thin cortex		1	1
Death before operation			4
Total	36 (52 %)	3 (4 %)	31 (44 %)

The only other complications we have seen were repeated slight intraventricular hæmorrhages in 1 case, and massive fatal cerebral thrombosis in 2 cases Most of our patients were well enough for discharge fourteen days after operation if drainage appeared satisfactory

Results

In following up cases of a disease characterised by insidious progress or spontaneous arrest, it is not easy to assess the effect which an operation has had Some of our cases which were steadily progressive before operation have remained static for between twenty and thirty-two months since It is this group alone which has been classed as successful A few of the cases seemed to progress for a time after operation but have since arrested *These have been classed as failures in our* series, though operation may possibly have prevented too much deterioration before spontaneous arrest

Assessment has been by frequent checks, in which clinical impression, head measurement, and (in the majority) repeated ventricular-pressure readings have made a decision possible In a few cases, dye-excretion tests and air studies have been used, and improved absorption or thickening of the cortex has been demonstrated

The problem of classification was simplified by the fact that all the cases which failed after having drained did so within four months of operation, and nearly all within two months All cases which succeeded for that length of time are still arrested, though *of* course it is impossible to say whether the arrest will be permanent

TABLE IV—CAUSE OF DEATH IN OPERATED CASES

Related causes	
Progressive hydrocephalus	7
Intracranial infection	3
Intracranial vascular thrombosis	2
Operative	1
Unrelated causes	
Gastro-enteritis	1
Inhalation of vomit	1
Intestinal obstruction	1
Unknown cause	1
Total	17

Of the 34 babies not operated on, hydrocephalus was arrested naturally in 20, as predicted *All these* are alive and well now, except 2 who died, 1 congenital heart disease and 1 of meningitis from an infected myelocele Of the 14 progressive cases, 12 are dead, and 2 not expected to survive long

Of the 36 babies operated on, hydrocephalus was arrested immediately in 13 and later in 5 These 18 are all still well (table II)

Tables III and IV show the survival-rates of the whole series and the causes of death in the cases operated on

Discussion

Little would be gained by comparing these results with those of other workers The criteria of success must differ widely in different series (here we are taking only the narrowest meaning—i e, arrest definitely coinciding with operation) Also, we have made no selection of cases, operating on all with progressive disease in whom it was technically feasible to do so This must have prejudiced results since many patients coming to operation were in an advanced stage of the disease We think, however, that this approach was the correct one, for the experience gained in treating these children is now proving of value in a more discriminating selection for a new series

In an attempt to devise a reliable method of selection, a dye excretion test for the subdural space has been worked out It was not used in the present series, but more recent work has shown a correlation between the percentage of dye excreted and the potential absorptive power of the space, and hence the prognosis for the operation in any particular case

The operation has a wide field of application, being suitable for the treatment of obstructive hydrocephalus wherever the site of the block Its sole requirement is a subdural space which will absorb sufficient cerebrospinal fluid and will continue to do so Therefore, success cannot be expected in the presence of a subdural effusion, and the space will rapidly lose its absorptive power if operation is performed in the presence of recent ventricular hæmorrhage or infection We have operated on patients whose cortex is almost paper-thin but, apart from other considerations, the technical difficulty of placing the disc without damage to the cortex makes these cases almost hopeless

In failed cases, it has usually been found that the disc, and sometimes the subdural space itself, have become occluded by adhesions More rarely, the disc has been found patent but the subdural space lined by a membrane and filled with unabsorbed fluid In either case, the cause can usually be shown to be due to the presence of blood or low grade infection

The fate of all the cases seen during the period of this series has been analysed to show that the success of the operation does not depend to any significant degree on natural arrest, since these cases have largely been eliminated before operation The figure of 36% success for the operation series, not in itself very striking, must be considered in the light of the total arrest rate of 52% for the whole series, and it must be remembered that the successes in the operation series were obtained from material from which many of the more favourable and only a few of the worst cases had been eliminated

In the next series we hope to be able to show that selection of cases will lead to more predictable arrest The number of operations performed is already large enough to show that, in a wide variety of hydrocephalic infants, arrest for a considerable length of time can be produced

Summary

An operation for hydrocephalus is described and a previous report amended The operation consists in the insertion of a plastic device through the cerebral cortex to provide drainage from the lateral ventricle to the overlying subdural space

A series of 36 operations on cases selected from 70 hydrocephalic infants is presented and the results discussed 13 of the operations seem to have arrested the disease

The results suggest that the method may be of value in many types of hydrocephalus, especially after selection by subdural dye excretion studies

We wish to thank our colleagues at both hospitals for their coöperation One of us (K M L) acknowledges the support of the research committee of The Hospital for Sick Children, Great Ormond Street Thanks are also due to Mr D Martin of The Hospital for Sick Children for fig 1 and to Miss J Hassell, the medical artist at the Westminster Medical School, for figs 2 and 3

THE TRANSFER OF BLOOD BETWEEN BABY AND PLACENTA IN THE MINUTES AFTER BIRTH

MAVIS GUNTHER
M A, M.D Camb
OBSTETRIC HOSPITAL, UNIVERSITY COLLEGE HOSPITAL, LONDON

IN 1801 Erasmus Darwin wrote

> " Another thing very injurious to the child, is the tying and cutting of the navel string too soon, which should always be left till the child has not only repeatedly breathed but till all pulsation in the cord ceases As otherwise the child is much weaker than it ought to be, a part of the blood being left in the placenta, which ought to have been in the child "

Since then many estimates have been made of the amount of additional blood which a baby may receive if the cord is not tied immediately Assessments have been made by weighing the baby (Haselhorst 1929, Allmeling 1930) and from blood volumes, and from the amount of blood obtainable from the placenta (DeMarsh et al 1942) Each investigator has found that a considerable proportion of the placental blood may flow into the baby or be trapped in the placenta according to the time of tying the cord

Present Investigation

Continuous records were made of the baby's weight in the minutes after birth so that not only the amounts of blood but also the events determining its flow could be examined

A semi automatic weighing machine was adapted to give a continuous record on a constantly moving drum indicating weight gain and loss The machine stood on an adjustable trolley and could be raised and lowered As soon as the baby was born he was put on to the pan in warmed blankets, and the recording pen was quickly brought near the centre of the chart by putting weights on the other pan. There was inevitably a delay, usually of 10–20 seconds, between the completion of birth and the start of the record

The instrument was so sensitive that the baby s movements caused an oscillation and a thickened record This had the advantage of showing the vigour of the baby's movements without obscuring the weight trend Large oscillations and interruptions in recording were inevitable during resuscitation and were sometimes also caused by the baby's movements

No attempt was made to hold up the flow of blood by constricting the cord while the record was interrupted or during the initial phase of getting the baby on to the pan Since at this stage the blood usually flowed rapidly to the baby, the total gains recorded were probably less than might have been obtained by holding up the flow then Recording usually continued until just before the birth of the placenta

Changes of weight were recorded in 39 babies born by vaginal delivery and 11 born by cæsarean section There were 33 boys and 17 girls The boys outnumbered the girls possibly because weighing was stopped at the outset through anxiety for the baby more often in the case of girls than boys

Pulsation in the cord was taken to indicate partial or complete patency of the cord arteries Because this was not seen to recur once it had ceased, blood was considered to flow only through the umbilical vein after cessation The records of weight change after vaginal deliveries showed that though the flow was mostly towards the baby, rapid loss from the baby to the placenta also often took place, sometimes but not often

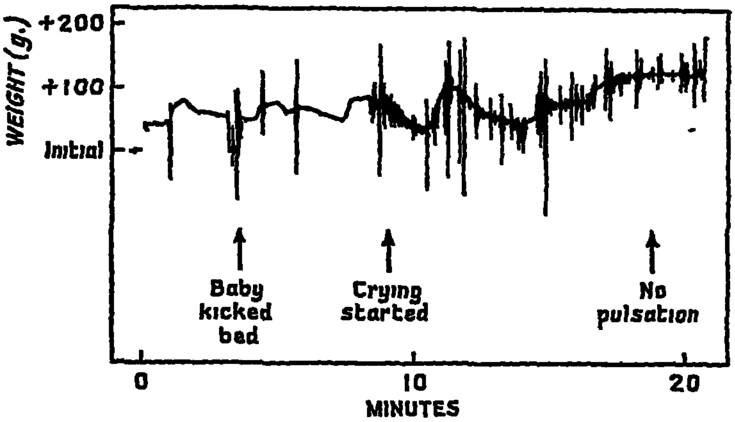

Fig 1—Weight changes in baby lying at level of vulva, with cord pulsating for 19 minutes Note weight changes induced by uterine contraction and relaxation

equalling or even exceeding the gain When the umbilical arteries were open, such loss may have been due to the pumping up of the placenta from the arterial side or be due to venous loss and no distinction could be found to indicate which was happening, except that where pulsation was present loss was more frequent

To find whether siphonage played any part in the interchange of blood, the weighing-machine and the baby were racked up and down to about 15 cm above and below the level of the mother's vulva when the baby's weight was steady

Figs 1–3 illustrate the events in three instances where the cord was pulsating during all or nearly all the period of tracing

In fig 1, with the baby kept at the level of the vulva, the successive gains synchronised each time with a uterine contraction, which was shown by the small increased loss at the introitus In this record the dominant effect of uterine tone is so clear that the baby's weight record had become virtually *a plethysmograph of uterine activity*

In the record shown in fig 2 two gains were accompanied by uterine contraction, but there was no weight loss even though the baby was raised and lowered, once stability had been reached

Fig 3 shows an instance where a baby who was slow to cry gained and lost and gained again before crying was established, the timing of the changes being different from those in figs 1 and 2

Fig 4 shows part of a tracing where pulsation had ceased and the weight, though still slightly increasing, was almost steady The baby was then raised above the level of the vulva (the broadened record represents the vibration of winding the pan up) *It will be seen that a loss of weight started as the baby's position was altered* and continued until the pan was quickly lowered to below the original level The succeeding gain when the baby was below the level of the vulva slowed as the baby started an outburst of crying, the subsequent tracing shows a slow steady gain The loss of 26 g and the gain of 58 g brought about by small hydrostatic changes due to the baby's position show how a baby may lose blood through being held above the level of the placenta In this instance the loss was cut short by altering the baby's height and was not necessarily maximal Clear evidence of loss and gain through venous siphonage was seen in 5 cases in the 19 where trial could be made

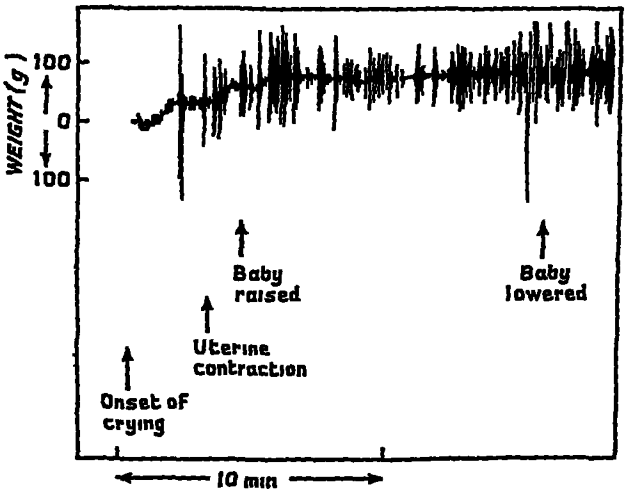

Fig 2—Stepwise weight gains associated with uterine contractions Cord pulsation throughout. No change resulted from raising or lowering baby.

The weight changes in 11 babies born by cæsarean section were recorded despite the difficulties of the circumstances The baby was put on to the pan and the weight charted intermittently between frequent phases of resuscitation (fig 5) (after its delivery the placenta was put in a tilted kidney-dish and taken, together with the baby and the apparatus, to another part of the theatre) These records are therefore less detailed They fall into two contrasting groups (fig 6)

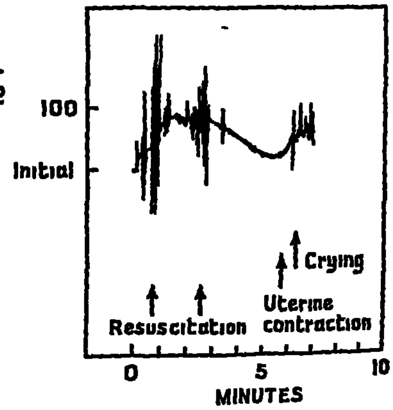

Fig 3—Large early weight gain succeeded by loss and small gain Cord pulsating throughout Baby at level of vulva

(1) 3 babies were large and vigorous and recording was continued conveniently The *increases observed* included 3 of the 4 greatest seen in this investigation (125, 130, and 180 g)

(2) In the other group the birth weights were, with one exception, under 3 5 kg , and the signs of vigour were delayed , so the recording was cut short, but even in the period of observation a stationary phase appeared to have been reached *None of these babies received more than 55 g* of blood

Discussion

These records confirm once more that, if the cord is left untied, a baby will usually increase his blood volume by a significant amount The weight of blood received by these babies, as in Haselhorst's (1929) and Allmeling's (1930) work, was roughly correlated to the baby's weight (fig 6), ranging from 0 8 to 4 7% of the body-weight If the blood of the neonate weighs about 10% of the body-weight the amount of blood involved can probably be more than 40% of the baby's blood volume

Little is known of what determines how much blood the baby's body will accept The amount of blood passing into the baby may be correlated to the baby's size because the size of the placenta is similarly related, and the amount of blood in the placenta depends on the size of the placenta The changing resistance of the pulmonary vessels at the onset of respiration in the maturing embryo (which has been found in sheep by Born et al [1955]) may be another contributary factor. Thin cords appear to go white and cold sooner than thick ones, and transfer ceases soon after the cord is white

The baby's size is not the only determining factor, because some of the records showed a cessation of flow while the cord vessels were still functioning, as if a main reservoir had been filled For instance, fig 4 shows that, after siphonage out, the blood flowed in fast at first when the baby was put below the level of the placenta, but, when the gain reached a point lying more or less on the projection of the original weight line, the gain slowed suddenly and continued as before from there In that case the loss and gain were known to be venous and the inflow was at a rate of 60 g a minute If the circulation time in a neonate is about 10 seconds (Lesser et al 1952), this addition to, and the earlier subtraction from, the circulation are relatively small, but the definite limit observed suggests that the filling may have been partly set, perhaps, by the capacity of liver, lungs, and spleen

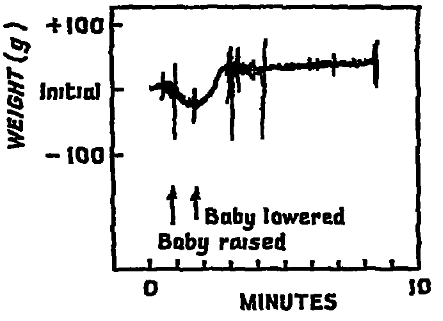

Fig 4—Loss of weight from siphonage when baby was raised and restoration when baby was lowered No pulsation of cord

The intake was also seen to be limited on a small scale by a certain sequence of events In many records a relatively steep gradient showing flow into the baby, as in fig 1, was followed by a burst of crying rather as, in transfusing a baby, crying is often induced by quickness of flow Sometimes the crying had little apparent effect on the rate of inflow, but more often the raised intra-thoracic pressure of crying could be seen to be damming back the venous flow or even to be driving blood into the cord vein at the umbilicus when the cord had been previously empty The immediate effect of crying may therefore be to slow the intake, yet the contrast between the two groups of babies born by cæsarean section implies that the lusty crying baby gains much while the baby not quickly putting its lungs into use gains little

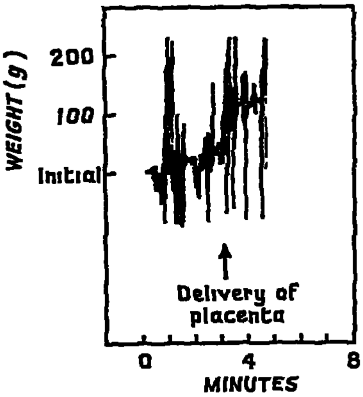

Fig 5—Weight after cæsarean section

We have, then, a picture of complicated hydrodynamics After vaginal delivery the force of the uterine contractions, known to be about 60 mm Hg in the second stage (Moir 1936), may squeeze the placenta The baby's systolic arterial pressure of 69 mm Hg (Holland and Young 1956) tends to distend the placenta and does so rapidly while the umbilical arteries are patent and the uterus is relaxed The blood in the umbilical vein is hastened towards the baby by uterine contraction but, when uterine tone is poor, may flow in either direction, which is determined by small changes in pressure, such as those induced by 15 cm difference in height (12 mm Hg) and by changes in intrathoracic pressure

In addition it is probable that the physiological mechanisms in newborn lambs described by Dawes et al (1953, 1955, 1956) and Born et al (1955, 1956) have their counterpart in man, and that the interplay of pressure changes and the patency of the foramen ovale and the ductus arteriosus and the calling up of autonomic effects by asphyxia with quickened umbilical arterial flow alter and are altered by the nett flow of blood

Most important of all, presumably, are the interaction and interdependence of the inflation of the lungs and the increasing circulation in them Jäykkä (1957), who subjected the lungs of stillborn babies to constant inflation down the trachea and constant reduced pressure surrounding the lungs, showed that the distension of the lungs was greatly aided by distending the pulmonary arteries (in his work at 80 mm Hg) It seems that, for the establishment of breathing, the ample filling of the right side of the heart and also perhaps reversed flow in the ductus should occur with the phases of attempts to distend the thorax Although the venous inflow is halted by the expiratory efforts of crying, over a period of time the distension of the lungs would be promoted by the existence of a reservoir to feed into the circulation

If the inflow is important not only for increasing the amount of blood but also for expanding the lungs, delay in tying the cord has to be viewed slightly differently With a brief delay the obstetrician may be helping the baby to 50 g of blood, with a longer delay there may be an alternation of events which benefits the child even more Possibly there is here a principle of intermittency.

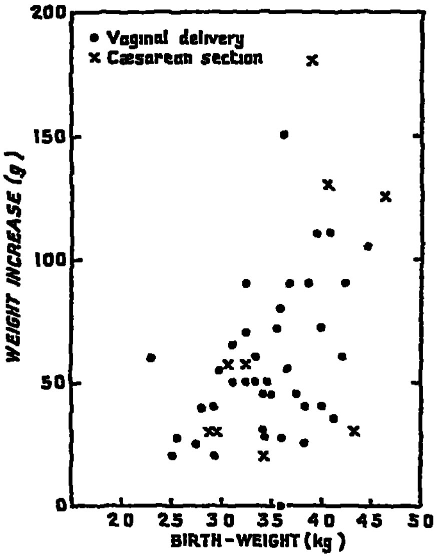

Fig 6—Relation of weight gain to birth weight.

Further work should show whether the incidence of pulmonary syndrome of the newborn can be reduced by allowing this reservoir to operate Bonham Carter et al (1956) have already shown that the child who survives the condition has the capacity to increase his caval pressure The added risk of pulmonary syndrome in delivery by cæsarean section (Bound et al 1956) may be due to the draining to which nearly all babies so born are subjected, because at cæsarean section the baby is usually held well above the mother's abdomen,

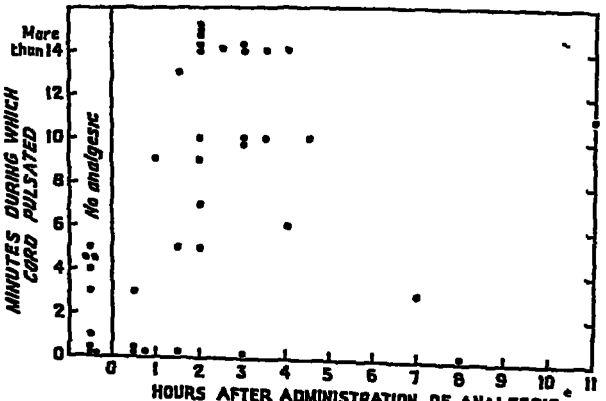

Fig 7—Relation of duration of pulsation of cord to administration o analgesics in labour

the intra uterine pressure being roughly that of the atmosphere The cord vessels are conspicuously distended Loss of blood into the placenta is almost certainly fast and large, and the baby loses not only what would have been transferred to him if tying had been delayed but also an additional amount flowing in both cord vein and arteries into the unsqueezed placenta Usually the cord is *cut near the baby*, a practice which deprives him also of the 10–15 ml of blood in it Many surgeons now hold the baby at table level to avoid siphonage Landau et al (1950) suggested delaying the tying of the cord and slinging the placenta in a towel above and beside the baby in the cot to allow passive transfer to continue

Siphonage and arterial loss are also almost inevitable when the mother is delivered in the lithotomy position and the baby placed on her abdomen, unless an oxytocic drug has been given Lohne (1943) recommended that babies delivered by forceps should be put below the level of the vulva This procedure is also probably very important to the first born of twins, at their birth the large relaxed uterus cannot be treated with oxytocics, for them the cord should be left untied until it is white and the uterus contracted, the baby lying below the level of the placenta

Holland and Young (1956) describe persisting low blood pressure in infants after breech and forceps deliveries and, more especially, after cæsarean section Their findings may well be a measure of the draining to which the babies are subjected where an analgesic is keeping the cord arteries patent, anæsthesia has relaxed the uterus, and the position of the baby is allowing siphonage I have been repeatedly surprised that the baby's condition gives no indication of the loss of blood into the placenta Obstetricians can so easily be unaware that blood is draining from the baby, and none would consent to the visible removal of 30–50 ml

One argument often put in favour of delayed tying of the cord is the tradition that the baby born before the arrival of assistance thrives In such a case the baby usually lies at a level lower than the placenta, the tying of the cord is not immediate, and the placenta (and the blood going to the baby) is kept warm in either the uterus or the vagina

In most deliveries nowadays we cannot imitate what appears natural, because analgesics (pethidine and chloral in this work) given to the mother during labour prolong the duration of pulsation in the cord Fig 7 relates the duration of pulsation to the administration of analgesics Since analgesics have such a definite action on the umbilical arteries, their possible effect on the closing of the ductus arteriosus and their effect on uterine arteries need to be reconsidered The incidence of postpartum hæmorrhage among women receiving one analgesic should be compared with a group receiving none rather than with those receiving another The delay between administration and its effect on the umbilical vessels presumably prevents the use of analgesics in the treatment of prolapsed cord

This investigation was first undertaken to determine whether delayed tying of the cord would provide fluid to tide the baby over the period of dehydration No clear evidence was obtained on this point, but certainly the additional blood is enough to be a significant contribution to the baby's nutrition 100 g is more fluid than a baby usually takes from the breast in the first two days, and the iron content is as much as the baby might be expected to get from milk in his first month

Fear has been expressed that the increased intake of blood would cause severe jaundice, but only 1 of the 50 babies developed severe jaundice It is unlikely that jaundice was prevented by increased renal secretion induced by greater fluid intake, because the weight losses in the first days of life were not unusual

Summary

The transfer of blood between baby and placenta was studied by continuous records of the baby's weight after normal deliveries and after birth by cæsarean section.

The transfer of substantial amounts of blood to the baby was confirmed, but large losses were also observed and were attributed to loss through patent umbilical arteries and by siphonage when the baby was held higher than the placenta

Three large vigorous babies born by cæsarean section gained very much, but the others little

Pulsation in the cord was prolonged if the mother had received analgesics

The findings are considered in relation to obstetric practice and neonatal respiratory physiology

My thanks go to Sister K M Billing and to the obstetric staff of University College Hospital for their help in this work, which was assisted by a grant from the Medical Research Council

ACUTE SUPPRESSION OF URINE AND LIVER FAILURE ACCOMPANYING ECLAMPSIA

DAVID SALTOUN*
M B Belf
LATE SENIOR HOUSE OFFICER

D D KINN
M B Belf
LATE HOUSE SURGEON

ASHTON UNDER LYNE GENERAL HOSPITAL

SUPPRESSION of urine may have many causes, and we do not always understand its pathogenesis It is a well recognised complication, but we do not know why anuria following eclampsia has hitherto been almost invariably fatal either directly or through further complications

Many cases of anuria treated conservatively have been described Most of those from departments of obstetrics and gynæcology have followed abortion, incompatible blood-transfusion, antepartum hæmorrhage, or postpartum hæmorrhage[2, 9–11, 16–19, 21, 23, 24, 26, 28–30, 34–37] Few detailed reports of anuria in eclampsia have been published, and a large proportion of the patients died[12, 19, 21, 24, 25, 29, 35, 36]

In the present case the patient developed anuria during eclampsia and was treated conservatively and recovered, probably because the renal failure was recognised early and conservative treatment, based on the lines of Borst, Bull, and others,[3–7, 13, 39] was started at once We have been unable to find any published report of a case of this type treated in this way

Case-report

The patient, aged 29, was admitted with severe pre-eclampsia at 9 20 P M on Feb 10, 1956 This was her third pregnancy, and she had borne two children Her two previous pregnancies had been normal and both deliveries spontaneous

---

* Present address West London Hospital, London W 6

There was no relevant medical history. She was 34 weeks pregnant and had had ankle œdema for the past three weeks and one episode of spots before the eyes. Both symptoms had subsided with rest in bed. She had had headaches during the past two days.

Examination

The patient was conscious. Her pulse and temperature were normal, and blood-pressure 220/120 mm. Hg. Œdema caused generalised puffiness of her face, and her finger rings were immovable. There was gross pitting on pressure from her ankles to half-way up her thighs. She had gross albuminuria, and her urine became solid when boiled. A single fœtus was palpable, with its breech presenting in the left sacro anterior position, and its size was consistent with the duration of amenorrhœa. The fœtal heart was regular. No abnormality was found in the other systems.

Treatment and Course

A basal anæsthetic dose of bromethol 6·3 ml. (0·09 ml. per kg. of estimated body-weight) in 217 ml. of water at 110°F was given rectally and repeated five hours later. Seven hours after admission the patient had an eclamptic fit, and a further 6·3 ml. of bromethol was given. There was a second fit at 7.45 A.M., and a further 6·3 ml. was given.

The blood pressure had fallen to 130/110 mm. Hg (fig. 1), and at 10 A.M. a stillborn female was delivered spontaneously.

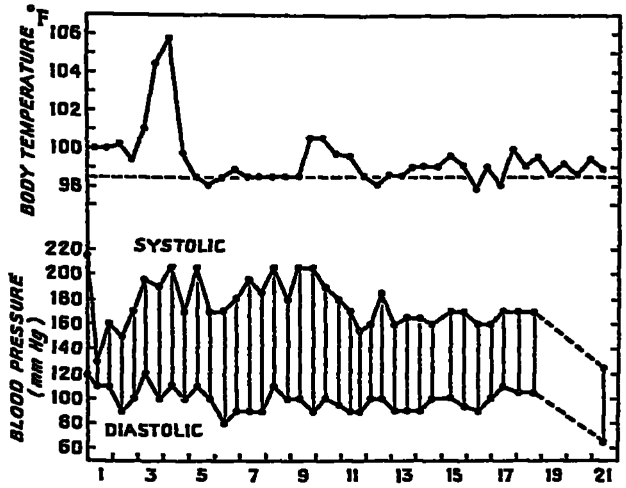

Fig. 1—Temperature and blood pressure.

The third stage was completed in five minutes, and there was no abnormal retroplacental clot. There was therefore no evidence of accidental hæmorrhage.

Post Partum

Large doses of sedatives (phenobarbitone sodium gr. 3 and paraldehyde 10 ml.) were given intramuscularly in the next few hours, and the blood pressure remained 130/100 mm. Hg. Seven hours after delivery the patient was jaundiced and had passed only about 8 oz. of urine since admission. Next day her blood urea level was 55 mg. per 100 ml. (fig. 2) and serum bilirubin level 22 mg. per 100 ml. (see table). The van den Bergh test gave a direct biphasic reaction. There were numerous red blood cells but no crystals or casts in the first specimen of urine examined in the ward by us. Subsequent laboratory examinations revealed casts in addition to the red cells.

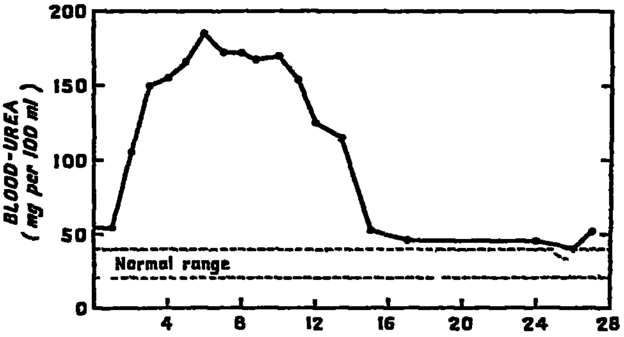

Fig. 2—Blood urea levels.

The day following delivery the patient remained unconscious. A catheter was kept in situ and was released hourly, to see whether urine was being secreted. It was felt that repeated catheterisation would be necessary, and that this would be more likely to provoke urinary infection than would a catheter kept in the bladder. The facts that the patient was unconscious and that it was necessary to save and measure all the urine influenced this decision. No urine was obtained in eight hours in spite of intravenous fluids, which were given as 25% dextrose 1 litre plus a quantity equivalent to the previous day's output (fig. 3). The blood chemistry was estimated daily (fig. 4). For the intravenous transfusions into the arm was substituted a polyethylene cannula in the inferior vena cava by way of the sapheno-femoral junction. Fluid requirements were calculated as before except that 40% glucose was used. Treatment with intravenous 40% glucose 1 litre a day provided 1600 calories. Amounts in excess of 1 litre were given as 5% dextrose. When the CO_2 combining power remained low, 1/6 molar sodium lactate was given from the sixth to the ninth day instead of some of the 5% glucose. An attempt was made to correct anæmia by transfusing packed cells. Intramuscular calcium gluconate was given because of the low serum calcium level.

On the third postpartum day the patient's temperature rose to 105·6°F. This was first treated by tepid sponging, which proved ineffective. She was then cooled with damp sheets, the draught from electric fans, and ice applied to her body and extremities. Aureomycin 250 mg. was given into the drip. Her temperature remained raised for five days before settling to normal.

On the fifth postpartum day diuresis began, the patient passing 1300 ml. of urine in twenty-four hours. The jaundice was noticeably less (serum bilirubin level 5 mg. per 100 ml.), and the patient spoke to the nurse for the first time. Her hæmoglobin was 55% (Haldane) (8·1 g. per 100 ml.) and 1 pint of packed cells was given slowly. This was not counted in the daily intake requirements.

Next day her general condition was improved and serum-bilirubin level was 2·2 mg. per 100 ml. She could take fluids by mouth, and the amount so taken was allowed for in calculating the daily requirements. From then on the amount of fluid given orally was increased until the intravenous route was discontinued on the ninth day post partum. A light diet was allowed but no protein until the blood urea level fell below 100 mg. per 100 ml. on the fourteenth day post partum. A low protein diet was then allowed. The jaundice disappeared, and the serum electrolytes and serum bilirubin levels returned to normal values.

LIVER-FUNCTION TESTS AND BLOOD-SUGAR LEVELS

—	Day after onset of failure									
	2	3	4	5	6	7	9	10	12	16
Liver function Tests										
Total protein (g. per 100 ml.)	4·9	4·5	3·5	3·2	3·2	3·8	4·3	4·8	5·1	6·2
Albumin (g. per 100 ml.)	2·5			1·7						
Globulin (g. per 100 ml.)	2·4			1·5						
A : G ratio	1·1 : 1			1·1 : 1						
Thymol turbidity (units)	2·5			2·5	2·5					
Thymol flocculation (units)				0	0					
Serum bilirubin (mg. per 100 ml.)	22·0	12·0	8·0	5·0	2·2	1·5				0·4
Prothrombin activity (% of normal)	70		81	72	72	72				
Plasma specific gravity		1·018	1·017	1·016	1·016	1·018	1·019	1·020	1·027	
Alkaline phosphatase (K-A units)	13·5			11·8	11·7					
Blood sugar (mg. per 100 ml.)	112			168	281	381	144	110	175	132

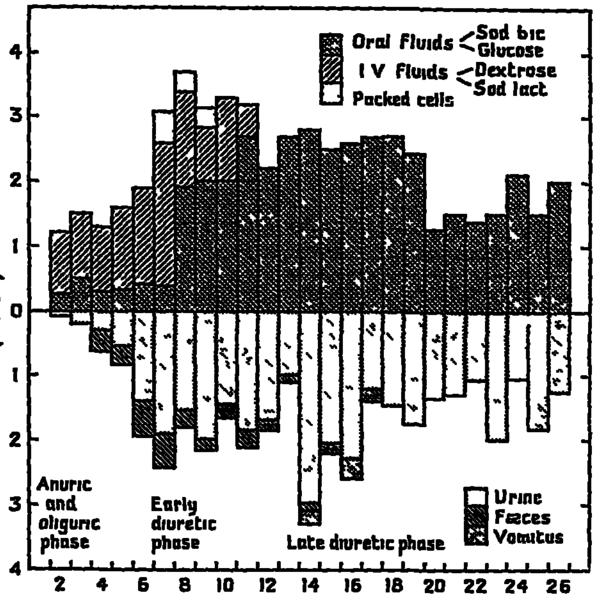

Fig 3—Fluid balance chart

On March 7 the blood urea level was 39 mg. per 100 ml., and the urea clearance test showed 45% of normal function in standard urea clearance. The specific gravity of the urine was 1·000–1·008. The patient was discharged on March 8, her blood pressure being 160/80 mm. Hg.

Follow up

The patient was readmitted a month after discharge. She was feeling well and had maintained her low-protein diet. Her blood-pressure was 125/90 mm. Hg. Her serum electrolyte levels and liver function tests were all within normal limits; her blood urea level was 35 mg. per 100 ml. Her standard urea clearance was 34% of average normal function, and her urine was concentrated up to 1·012.

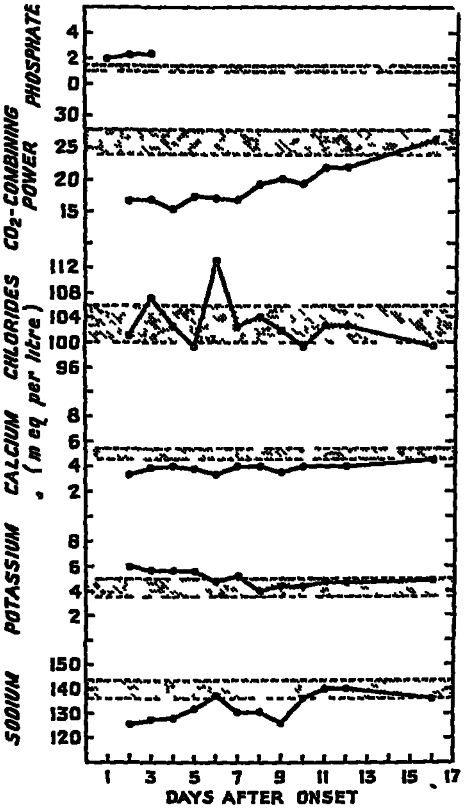

Fig 4—Serum-electrolyte levels. Shaded areas represent normal range.

Three months afterwards the specific gravity of the urine was 1·002–1·020 and the standard urea-clearance test 51% of normal function.

DETAILS OF TREATMENT

Liver and Kidney

The patient was first noticed to be jaundiced and oliguric seven hours after delivery, while still comatose. The small amount of heavily blood-stained urine and the accumulation of bile pigments in the plasma indicated renal and hepatocellular damage. To protect the liver and kidneys, a 25% glucose infusion was started into an arm vein, and 1 litre was given in twenty-four hours. Digoxin was added to this because of the congestive failure shown by the raised jugular venous pressure and gallop rhythm.

Thirty-six hours later it was realised that this situation might continue for some time, and the infusion into the arm vein would not be able to continue indefinitely because of the risks of local thrombosis and inadequate caloric intake. Accordingly it was decided to give fluids into the vena cava. Therapy by glucose/peanut oil intragastrically was not contemplated, because of coma and possible vomiting. The inferior vena cava was chosen because access to it by cutting down on to the saphenous vein close to the sapheno-femoral junction was thought to be easier for those inexperienced in the technique. Moreover only ordinary polyethylene tubing was available, whereas a proper cardiac catheter was thought to be essential to pass the subclavian arch to reach the superior vena cava. However, since then it has been pointed out (G. M. Bull, personal communication, 1957) that it is quite easy to put a polyethylene tube into the superior vena cava via the antecubital vein. It is just pushed until roughly the right length is in, and then its position is checked by manometry as follows: if there is an inspiratory lowering of pressure it is in the thorax or the neck; if an inspiratory rise it is too far (in the inferior vena cava). If it is in the neck a Queckenstedt sort of test will reveal this; if in the right ventricle there will be a higher mean pressure than there should be.

It is neither hazardous nor difficult either to set up or to *maintain an infusion into the inferior vena cava*. Considerable discussion and speculation preceded our use of it, but experience soon showed it to be quite simple.

Since the patient was not fit to be moved, the operation was done, with her in bed in her side ward, under fully aseptic technique. Through a two-inch incision the upper end of the left saphenous vein was exposed and the distal part ligatured. A no. 4 polyethylene tube was introduced into the proximal end for about ten or eleven inches and tied in with a double catgut ligature. A further deep nylon suture was inserted and tied over a gauze pad. By this means the patient's intake of fluids and calories was maintained for seven days. Heparin 2500 units per litre was added to the drip as a harmless and necessary precaution. Prophylactic aureomycin 250 mg. daily was given, sometimes by direct injection into the polyethylene tube, and at other times it was added to the transfusion bottle. It has since been realised that we gave too much aureomycin and risked getting dangerously high blood levels in a patient whose glomerular filtration mechanism was not working. A more rational régime, which would be followed in a future case, would be to give a loading dose of 1 g. aureomycin and thereafter 250 mg. every four days, or alternatively to stick to the simpler and safer penicillin, given as 1 mega unit followed by 0·25 mega unit on alternate days. The need for preventing infection at this stage has been emphasised by Bull[5] and others.

In dealing with a case of this severity for the first time it is necessary to keep very accurate fluid balance charts; and it is important that one member of the team should be responsible for sending specimens of blood to the laboratory at the same time each day, receive the results personally, and provisionally order treatment for the next twenty-four hours. This minimises the chance of confusion, as has been pointed out by Scott Russell et al.[27]

Renal failure was recognised early, but a prompt decision to start treatment cannot be overemphasised. This is more likely to succeed when the complication is anticipated.

Hyperpyrexia

When her temperature reached 105·6°F on the third day the patient appeared moribund. Energetic measures were needed because ordinary tepid sponging had not helped. She was stripped and covered with a wet sheet, and the draught from open doors and windows was augmented by electric fans. Her limbs and trunk were then packed with plastic theatre caps filled with ice cubes. As the covering sheet became dry it was easily moistened by cold water from the ice bags.

A small brain stem hæmorrhage following the eclampsia was considered to be the cause of the hyperpyrexia.

Eclampsia

The only deviation from the usual therapy of bromethol and general nursing was that bromethol was repeated on three occasions after the first dose—i.e., a total of 26·2 ml. in about twelve hours, including an unknown amount that was not retained. This was possibly excessive and may have been responsible for some damage in a liver already affected by eclampsia Slow detoxication of the bromethol may have added to the subsequent coma

Morris[22] did not find evidence that oliguria was a complication of bromethol treatment

Electrolyte Balance

The deviation from normal of the blood electrolyte levels was fairly severe, but they never reached levels of extreme danger Some were nevertheless abnormal enough to merit comment

Potassium —The initial hyperkalæmia was effectively controlled by the protective action of the hypertonic glucose,[5] and alternative measures were not required Hyperkalæmia is always to be feared, it prolongs the PR interval and lengthens and elongates the Q R S segment An electrocardiograph is necessary to demonstrate these changes[33, 38] Hyperkalæmia may be minimal, but the excess potassium in the blood may have been sufficient to act harmfully on the heart Such damage may be detected electrocardiographically, whereas estimation of the serum potassium level alone might not show sufficient abnormality to suggest myocardial changes resulting *from* it *Digoxin* should then *only* be given if congestive failure is severe and there is no sign of reduced myocardial conductivity

Alkali reserve —The acidosis persisted until sodium lactate was given intravenously Sodium lactate could perhaps have been given at an earlier stage to this patient, but the question arose of administering sodium to an œdematous patient It was considered wiser not to give it as lactate intravenously in the early stages but to wait and see if the acidosis would correct itself When this did not happen, even after concentrated sodium bicarbonate had been given orally, we decided to observe the effect of 1/6 molar lactate, estimating the alkali reserve daily The response was good (fig 4), and there was no sign of retention of sodium, but much of the œdema had subsided by the time this stage was reached There is controversy *about* whether *sodium lactate should* be given to correct acidosis in the presence of œdema, we steered a middle course without disadvantage We feel that each case should be judged on its merits, and, if sodium lactate is given, one should be ready to stop it whenever signs of retention of sodium appear

Calcium —The serum calcium level fell and tetany was feared Therefore 10% calcium gluconate 40 ml was given daily The intramuscular route was chosen as being safer than the intravenous The hypocalcæmia is compensatory to retention of serum phosphate when there is no renal function, and was to be expected Calcium has an effect on the myocardium about opposite to that of potassium, it therefore seemed logical to give calcium to the patient

Blood transfusion

When the hæmoglobin was found to be *55%* (8 1 g per 100 ml), a pint of packed cells was given Opinions differ about whether this should be done, Bull[8] being in favour and Sheehan[33] against No rise or fall in serum potassium level was detected after the transfusion

Vena cava Infusion

The vena cava infusion was stopped after seven days, when the patient had recovered clinically but the specific gravity of the urine was still only 1 010, showing that selective reabsorption had not yet been restored, although glomerular function was adequate Subsequent renal function may have been improved had this infusion been maintained another week, but some authorities suggest that concentrated glucose solution may have toxic effects on the kidneys For that reason it was discontinued as soon as possible

Signs of liver failure following eclampsia are uncommon, and the cause is obscure, but a large supply of glucose is known to exert a protecting influence An adequate intake of vitamins was given, as recommended by Bull[5]

PROGNOSIS

Eclampsia

The recurrence rate of eclampsia alone is about 10%[14]

Renal Function

Since the patient can concentrate urine to 1 020 and the urea clearance rate is rising, the prognosis for the renal lesion is favourable Eclampsia does not appear to cause permanent renal damage[15] An insufficient number of women have yet recovered from acute suppression of urine for a more accurate prognosis to be given

Liver function —This quickly became normal, and the regenerative capacity of the liver is well recognised

Discussion

It is now generally agreed that the conservative régime should be started as soon as anuria is recognised, so that the patient's *milieu interieur* never becomes so abnormal that she dies before renal function is restored This treatment is rational because the kidneys of patients who die on the eighth to twelfth day of anuria commonly show active regeneration of tubular cells in the injured areas Anatomical and functional repair of the kidneys may take place if the patient can be kept alive long enough Treatment aims at reducing the breakdown of cell protein to a minimum, thereby diminishing the rate of accumulation of metabolites—e g, urea—and of potassium in the blood It is the increase in extracellular potassium which usually kills the patient[5]

Ætiology of Anuria

The general medical and surgical causes of anuria have been enumerated,[13] and the obstetric ones analysed[8, 33, 35] Terminology used in defining anuria has varied between anatomical, symptomatic, and ætiological Among the names used more or less synonymously have been the following acute renal tubular failure, lower nephron nephrosis,[20] acute tubular necrosis, acute nephrone nephrosis,[1] crush syndrome, transfusion kidney, and traumatic uræmia Possibly the name of choice, when eclampsia is involved, is merely " acute suppression of urine," because it involves no theory of pathogenesis

When anuria in obstetrics is classified into ætiological categories of shock, excretion of abnormal pigment, and circulating nephrotoxic substances,[35] it is at once seen that all the causes except eclampsia would easily find their place in a list of the general medical and surgical causes of anuria some (e g, accidental hæmorrhage, postpartum hæmorrhage, ruptured uterus, incomplete abortion, and ectopic gestation) are similar to such causes, and others are medical conditions that happen to obstetric patients (e g, incompatible transfusion, hæmolytic drug-reaction, sulphonamide or quinine sensitivity, mercurial poisoning, and septicæmia) Thus pathogenesis of the " shock " causes may be explained as renal ischæmia and its nine grades of lesion according to degree and severity,[31, 32] that of the other causes being damage to tubular epithelium by pigments and toxins preventing selective reabsorption of the glomerular filtrate, but where eclampsia comes in this classification is uncertain Slowinsky[35] puts it among the nephrotoxic agents as " ? toxins of eclampsia and pre eclampsia " But what the toxins are is unknown, and where they exert their influence is undiscovered Until further light is shed on the subject, it could be suggested that renal failure in the present case of eclampsia followed the pattern of that in shock, the renal ischæmia arising from spasm of the renal arterioles and capillaries

The rôle of the hypothetical toxin is unknown We are certain that our patient did not suffer enough shock to make her anuric, because her blood-pressure was always above normal There was no evidence of concealed accidental hæmorrhage[40] either before she became unconscious or after delivery, and she did not have a postpartum hæmorrhage Blood-transfusion, sulphonamide, and quinine therapy were never used, and there was no evidence of any other intoxication We conclude that her renal failure could only have been of eclamptic origin

The cause of renal failure is leakage of glomerular filtrate through the walls of the damaged tubules instead of being concentrated and transported by them

It has been said that the importance of oliguria and anuria in obstetric cases may sometimes have been unrecognised previously This may be due to the overwhelming nature of other aspects of the case, the speed with which patients succumbed, or the lack of standardised rational routine of treatment

Summary

A case of fulminating pre eclampsia progressing to eclampsia and stillbirth while under bromethol therapy is described

Renal and hepatic failure followed, the patient remaining unconscious for five days

Her brain-stem appears to have received damage, which was reversible

Concentrated glucose was given into the inferior vena cava, the electrolyte equilibrium was carefully controlled, and hyperpyrexia was reduced by physical cooling

We wish to thank Mr T. B FitzGerald for permission to publish, Dr D A K Black for helpful advice during treatment, and the nurses for the skilful attention they gave this patient

Reviews of Books

William Harvey

His Life and Times His Discoveries His Methods LOUIS CHAUVOIS, Laureat de l'Institut et de l'Academie de Medecine London Hutchinson Medical Publications 1957 Pp 271 25*s*

IN this tercentenary year of Harvey's death, many doctors and medical students will want to learn more of his life and times, his discoveries and his methods, and in this book Dr Chauvois, a distinguished French physician and medical historian, has provided exactly what they want He has carefully studied and sifted all the available information, and he has inspected all the memorials of the great man An accomplished scholar, he has also examined the Latin texts of Harvey's published writings From these materials, his balanced judgment has produced a life-like portrait of the man and the scientist He has not hesitated to use deliberate fiction when that can be done without going too far from probability Thus, he describes a journey from Padua to Venice when, *as an* undergraduate, Harvey reviewed and criticised in his mind current ideas about the circulation of the blood, and there is an account of a typical day with Harvey in the year before *De Motu Cordis* was published There are some factual errors in the text, but they detract little from its merit

Much of the text is quoted from D'Arcy Power's biography, but Dr Chauvois is sometimes critical of Power's views For example, he insists that it is not enough to read Harvey's book to appreciate properly his teaching, and that the two letters to the unbelieving Riolan, written in 1649, are even more important Power and others believed them to be of secondary interest

> "In the Letters we have the same affirmations, the same demonstrations of the way the heart works, of the functions of the arteries, of the return of the blood by means of the veins—in a word, the same description of the circuit but with overwhelming answers to all possible objections Despite his seventy one years Harvey still shows himself to be an admirable dialectician, though one who always relied upon observation and upon carefully executed experiments"

This important and very readable book, written with much charm and well illustrated, deserves many readers

Methods in Enzymology

Vol III Editors SIDNEY P COLOWICK and NATHAN O KAPLAN, McCollum Pratt Institute, The Johns Hopkins University, Baltimore, Maryland New York Academic Press London Academic Books 1957 Pp 1154 $26 00

THE third instalment of this Herculean publication surpasses by some 200 pages the larger of its two predecessors A subtitle says that it is devoted to the preparation and assay of substrates, and this definition includes, of course, most of the organic compounds found in living matter Much of the book, therefore, has interest and application outside what might be regarded as the rather esoteric province of the pure enzymologist Thus, the discussions of analytical procedures for the nucleic acids, sugars, amino-acids, and lipids provide excellent introductory reading for anyone faced with estimating one of these substances for the first time Quite apart from forming a valuable new unit in the series to which it belongs, this book is a helpful source of information on many topics in quantitative biochemistry The final volume promises to deal with biochemical methodology in a still more general way

Dextran and its Use in Colloidal Infusion Solutions

ANDERS GRONWALL, M D professor of clinical chemistry, University of Uppsala Stockholm Almqvist & Wiksell Oxford Blackwell Scientific Publications 1957 Pp 156 20*s*

A PLASMA substitute must be a *harmless colloidal* solution of a substance whose molecular size gives it an appropriate osmotic pressure in the blood-vessels Dextran is a viscous polysaccharide produced in cultures by certain micro organisms, particularly some leuconostoc species By purification and degradation processes, dextrans can be prepared which are useful plasma substitutes for intravenous infusion, and this book is an excellent account of the development of clinically useful dextrans and of the historical background Chemical and physical theories are clearly enunciated, and clinical applications and toxic manifestations well described Despite some awkward passages of translation the style is generally very clear

---

Current Therapy (Philadelphia and London W B Saunders 1957 Pp 690 £3 17*s*)—The new edition of this annual, edited by Prof Howard F Conn, has nearly succeeded in the almost impossible task of keeping itself fully up to date thus, though perchlorate for hyperthyroidism and hypophysectomy for breast cancer are not mentioned, there are good accounts of the hypoglycæmic sulphonylurea compounds and the newer hypotensive drugs Its scope encompasses all non surgical disease and a few surgical and obstetric conditions The authors' recommendations are in the main dogmatic and orthodox, though the account of treating venous thrombosis by surgical removal of the clot is intriguing The list of ingredients in commercial products could be invaluable in a poisoning emergency

THE LANCET

LONDON SATURDAY, JUNE 22, 1957

How Many are Chosen?

WITH the post-war ex-Service bulge behind them and with the prospect from 1960 onwards of a considerable increase in the numbers reaching the age of 18, the Committee of Vice-Chancellors and Principals has prudently taken stock of the relative numbers of successful and unsuccessful applicants for university entrance in the recent past. In 1952 they appointed a subcommittee, with Sir JAMES MOUNTFORD, of Liverpool University, as chairman, to investigate the nature and fate of applicants for entry; after careful planning, a detailed survey was made of applicants and entrants to almost every university in the United Kingdom for the session 1955–56. The main object was to ascertain "whether the number of places was inadequate, adequate, or in excess"—a matter of interest to parties as diverse as the Chancellor of the Exchequer and the heads of schools as well as to university staff. Fortunately the scope of the inquiry was widened to obtain "information about the previous educational background of the applicants, their social classification, the sources of their financial support, and the careers which at the time they made their application they proposed to pursue." The subcommittee's report[1] written by Mr R. K. KELSALL, and published last week is described in the *Times* by Sir JAMES MOUNTFORD[2] as "based on the first large-scale investigation of its kind ever attempted," and thus "a matter of considerable public interest." The figures now made available bring some precision into an area previously occupied only by opinion, or rather by opinions; for some thought that worthy applicants were being turned away in droves, while others thought that every suitable applicant would find a place, though not necessarily in the university of his first choice. As the preface to the report says, "Opinion, in a matter of this kind, is no substitute for facts."

Of 31,000 applicants, about 18,000 were admitted in October, 1955; the 13,000 applicants not admitted included 2000 from overseas. Of the 11,000 home applicants who did not succeed in 1955 no less than 4000 had been accommodated by October, 1956; and of the remainder, about half had failed to enter not as the result of an arbitrary decision, but through sheer lack of the minimum educational requirements for entry. There was, it is true, a residuum of 2000–2500 applicants who had obtained the minimum requirements for entry but had not gained a place; and there was a similar number of unfilled places; but unfortunately the vacant places were mainly square and the candidates round, or vice versa. A substantial number of places—over a thousand—was vacant only by default, having been offered to applicants who had gone elsewhere. The general picture, with 94% of available places filled, is not unsatisfactory. As Sir JAMES MOUNTFORD says: "It is not reasonable to expect that places and applicants can ever be so perfectly matched that there will be no vacancies; nor is it to be expected that universities will feel it right to accept every applicant who has secured just the minimum of marks to bring him into the category of 'qualified' as that term has necessarily had to be used in this inquiry." The *Manchester Guardian*[3] stresses the low proportion of "working-class children" among the applicants (28–30%, compared to 72% of manual workers in the adult male population). Fortunately, there was no material difference between the proportion of manual workers among the parents of those admitted and those not admitted; so discrimination by the universities could be ruled out. The report also gives evidence that hereditary factors are much less important than the combined effect of "differing environmental influences and parental aspirations"; and the *Guardian* draws one possible moral—that these are "circumstances that will have to be overcome."

The medical reader will naturally be curious to know how the applicant for a medical course compares with other applicants in his social background, his previous education, and—more critically—his hopes of admission. Those who claim that medicine is no longer a popular choice of career can draw no bitter confirmation of their views from the 1955 figures. Multiple application was commonest among medical applicants, and failure to accept a place when qualified to do so was rarest. Among the sons of doctors, 51% of those admitted were entering the medical course; and doctors' sons made up 17% of male medical students. Among medical students, a lower proportion had been to local-authority schools, primary or secondary, than among students of other faculties; and fewer medical students were receiving financial assistance. The percentage of manual workers among the parents of medical students is low (16–20%), compared with the parents of science students (33–35%). The chance of admission to the medical course in 1955 can be inferred from table I of the report which gives the required increase in places for admission of all applicants in medicine as 48%; in other words, 2 out of every 3 applicants were placed at the time and university of their choice. This is probably a reasonable figure, for many of the rejected applicants were placed in the following year, or were on the other hand lacking in the minimum requirements for entry. It would appear, in fact, that the medical schools are not at present compelled to turn away too many of their applicants, while on the other hand there is still a need and an opportunity for selection. The pressure for entry (and perhaps for expansion) can be expected to increase after 1960; but the number of applicants cannot be the sole criterion of the number of entrants. The staffing and accommodation of medical schools in general is scarcely adequate for our present numbers. This can no doubt be improved, but the process is unlikely to be sudden in its accomplishment or effects. Moreover, while we now have a better answer than ever before to the question "How many intending students are we likely to get?", we still have precious little solid information on the other end of the course—

"How many doctors do we need?" For that, we hopefully await the report of the Willink committee, set up in 1955 "to consider the future numbers of medical practitioners and medical students"

Night Vision

In peace-time the city-dweller has very little occasion to use his night vision and (as was revealed in the first few nights of the blackout in the late war) may suffer from some degree of night blindness without ordinarily being aware of the fact In the 1914–18 war poor night vision was apparently not a serious problem for the Allies, but it caused a good deal of anxiety in the armies of the Central Powers In the 1939–45 war the demands on night vision made by the rigid blackout and by night flying brought the problems of seeing in the dark into sharp prominence, and much work has since been devoted to the subject

When, in the years between the wars, the association between poor dark adaptation and vitamin-A deficiency was finally established, tremendous interest in night vision and the means of testing it suddenly developed Much work was done on dark adaptation and night vision in an attempt to find some satisfactory means of evaluating the extent of possible vitamin-A deficiency in various populations Unfortunately, by far the greater part of this work was unsatisfactory, owing to the incursion of workers from other specialties into the highly complex field of visual research Consequently a number of workers, notably in America, Denmark, and this country, concluded that large sections of the population had some degree of vitamin-A deficiency—a conclusion that was not supported by other workers[1] whose investigations were more carefully controlled One among the many causes of confusion was the uncritical use of two different criteria of dark adaptation One of these is the sensitivity of the eye to light as such—in other words, the ability to recognise whether a test patch is illuminated or not—while the other is visual acuity at very low illuminations More recent investigations[2] have revealed no correlation between the results obtained by these two methods, and the impression has gained ground that to estimate visual ability for some specific task it is necessary to devise a test bearing the closest possible similarity to the anticipated field conditions If correct, this means that there can be no one generally satisfactory test for night vision

The Medical Research Council has now published the report[3] of an extensive investigation of night vision in young subjects Both the absolute sensitivity to light and the visual acuity at low illumination were tested in the same people A carefully checked and rigidly controlled method of measuring the dark adaptation and the absolute sensitivity was found to give satisfactorily reproducible results and to be relatively simple in operation, but some training was necessary before reproducible results could be obtained with two very different visual-acuity tests After such training, however, there was a high correlation between the performances on these tests and those on the simple sensitivity test But this correlation held only for visual acuity at scotopic levels, at higher illuminations other factors complicate the picture The authors of the report therefore claim that a carefully devised sensitivity test can be used as a measure of night vision, or at least of potentiality for performing visual tasks at low illuminations after suitable training Their discussion of the reasons why they were able to obtain a correlation between visual sensitivity and what they call visual perception, whereas such careful and experienced workers as CRAIK and VERNON could not, is convincing

Obviously performance in the field—for instance, on the bridge of a ship—cannot be accurately predicted from knowledge of the person's visual sensitivity in the laboratory, too many extra psychological and other factors are involved As the authors themselves point out, a high visual sensitivity does not of itself ensure good perceptual efficiency On the other hand, a good perceptual efficiency requires a high sensory efficiency, and the latter can be measured in the laboratory It seems, therefore, that tests such as those described could at least be useful in picking out candidates with poor sensitivity who will always be unsuitable for exacting visual tasks at low illuminations

Serum-cholesterol and Myocardial Infarction

SEVERAL recent studies have added precision to our knowledge of the levels of cholesterol in apparently healthy men and women living in various countries In general, these studies have confirmed earlier views that myocardial infarction is often associated with high levels of serum-cholesterol, but they have added little to the understanding of the association between coronary-artery disease and disturbance of lipid transport in the blood

LAWRY et al,[1] in Boston, investigated 1508 men and 412 women, of whom most were resident in New England but a minority came from New York, Chicago, and other parts of the United States All were active and well by certain pre determined criteria Blood from 273 men who had had myocardial infarction and 141 men with definite angina pectoris was also examined In addition to serum-cholesterol the serum S_f 12–20 and S_f 20–100 lipoproteins were estimated by flotation methods LAWRY et al remark on the wide range of serum-lipid values in large groups of people of the same sex and age and with similar health status Individual values are thus of limited interest, but much can be learnt from mean values for groups For men the mean serum-cholesterol value at age 25–29 was 212 mg per 100 ml Thereafter the value rose steadily to a maximum value of 245 mg spread over the years from 45 to 59 After 60 there was a slight fall The mean values for women were about 20 mg lower than those for men up to the age of 45 Thereafter the means for women

[1] Lawry E Y, Mann G V, Peterson, A Wysocki A P, O Connell, R, Stare F J *Amer J Med* 1957, 22, 605

continued to rise, and for the age-group 60–69 the mean was 263 mg. For men aged 30–39 with acute myocardial infarction the mean level was 301 mg.—74 mg. above the mean for the healthy group of the same age. As age advanced, mean levels in the patients fell: the difference between the means of the patients and the healthy subjects diminished and was only 18 mg. at 50–59 years. The means for patients with angina pectoris were only slightly above the normal values. Only in patients with myocardial infarction who were younger than 40 were the mean figures very much higher than those for the controls. Tables show that after a myocardial infarction many older men have a serum-cholesterol value no higher than the mean for the control group. A smaller study in Malmö, Sweden, gave very similar results.[2] Apparently healthy Swedes have slightly lower values than the Americans, with a maximum of 230 mg. per 100 ml. in the age-group 50–59. Patients with myocardial infarction have a much higher serum-cholesterol than the control group up to the age of 50, but between 50 and 59 the difference is only just over 10 mg. In a large study in New York[3] the sera of 1200 apparently healthy men and women were examined. The cholesterol levels for the men were very similar to those in the Boston series, with the mean reaching a maximum of 247 mg. per 100 ml. at the age of 40. In the New York series girls up to the age of 20 have higher levels than boys; then up to 45 years the figures for men are higher; but after the menopause the figures for women continue to rise, with a maximum of 260 mg. at 60 years.

The Boston group point out that, although all these figures have been obtained on apparently healthy people, they do not necessarily represent normality, for myocardial infarction is endemic in the United States, as it is in Sweden. They add that a strong argument can be developed for the contention that the normal serum-cholesterol level in men is 150 mg. per 100 ml. This view is supported by a study in Israel, by Dr TOOR and his colleagues, which appears on an earlier page of this issue. These workers show that, in recent immigrants to Israel from the Yemen, mean serum-cholesterol levels for men vary from 145 to 158 mg.; in women after the menopause a maximum of 190 mg. is reached. In Yemenite immigrants who have lived twenty years in Israel, levels are much higher and the means for men have a maximum of 210 mg. in the 55–64 age group. These early immigrants lead a life which resembles more closely that of the U.S.A. and Western Europe; they also have a high mortality from myocardial infarction. The recent immigrants, who are poor Asiatic peasants, have a very low death-rate from this cause. In a letter this week Dr BRUNNER and Dr LÖBL also report low levels of serum-cholesterol in Yemenite immigrants to Israel, whereas Jews whose ancestors had lived for many years in Europe, the United States, or South Africa and were habituated to the manner of life in these countries had much higher levels (mean at age 46 years 231 mg. per 100 ml.)—the same as those usually found in their country of origin.

The Boston group found that neither S_f 12–20 nor S_f 20–100 values had any clear superiority over cholesterol values in predicting manifestations of coronary heart-disease. Nor could any useful combination of the three values be found. They also found that in over-weight people the contribution of "body fatness" to lipidæmia was significant; but the magnitude of the contribution was small, and they conclude that it can scarcely be of more than minor significance in the overall regulation of serum-lipids.

These observations on serum-cholesterol levels come from well-planned surveys in different parts of the world. Each is consistent with the hypothesis that the level of blood-lipids in man is artificially raised in successful modern civilisations. This disturbance of the lipid transport system appears to be an essential condition for myocardial infarction to become endemic in a people. Clearly the disturbance does not cause infarction, but only predisposes to it; the immediate causes of infarction remain unknown. But these observations provide firm evidence that the many studies now being carried out to determine the effects of different dietary fats on levels of serum-cholesterol are relevant to the prevention of myocardial infarction.

Annotations

BREATHING EXERCISES

IF owning that we do not know is the beginning of knowledge, then such a beginning was evident at a meeting of the section of physical medicine of the Royal Society of Medicine on June 12. Whether the benefits of breathing exercises are due to the exercises themselves or to the encouragement and attention that goes with them is disputed, and no acceptable controlled trial has been published. It is hard to get homogeneous material in so variable a disease as emphysema, and a double-blind trial of exercises is impossible. Dr A. C. Dornhorst proposed the use of such objective measurements as vital capacity, tests of ventilatory capacity, and timed vital capacity. He said that patients with emphysema should start deep breathing when they expected exercise and dyspnœa. Dr J. L. Livingstone, a firm believer in breathing exercises, reported many cases in which cure of asthma had followed a course of exercises, and thought that teaching patients to use the lower chest and epigastrium improved their condition and, especially in children, helped to prevent deformity. Dr D. A. Brewerton was less impressed with the value of such exercises; he emphasised that breathing exercises were of little use for patients before abdominal operations, but that postural drainage was valuable after inhalation of isoprenaline.

Many speakers agreed that there was little or no change in objective measurements after a course of exercises; that advice was more important than exercises; that harder and consciously prolonged expiration, and slower breathing, were often helpful (especially in asthma, where they might abort an attack); and that singers could hold a note longer after training. There was less agreement about the possibility of diaphragmatic spasm or of learning to use any group of intrinsic respiratory muscles in isolation.

We can be sure that, by means of physiotherapy, many patients achieve better posture and coordination, are encouraged through feeling that something is being done, and learn when to breathe out and when to breathe deeply. But we remain ignorant of whether breathing exercises as such are helpful.

THE ELECTROCARDIOGRAM IN MITRAL-VALVE DISEASE

THE *electrocardiogram in disease of the mitral valve* reflects the effects of the lesion primarily on the left atrium, and secondarily on the right ventricle (in pure or dominant stenosis) or the *left* ventricle (in dominant incompetence) Appreciable left atrial enlargement and hypertension is reflected in the character of the P wave, which is widened and notched but of normal amplitude [1] This widening and notching is present in most severe cases of mitral stenosis in sinus rhythm, but not in slight cases [2] When pulmonary hypertension is present, the P wave may become augmented in amplitude, reflecting right atrial hypertension, and enlargement of both atria may be revealed by a tall, broadened, and notched P wave Persistent atrial fibrillation, however, is present in roughly 45% of all cases of mitral-valve disease [2]

Since mitral stenosis is one of the commonest causes of right ventricular hypertrophy in acquired heart-disease, the cardiogram often shows evidence of this [3] The pulmonary arterial pressure and arteriolar resistance has been shown to be related to the left atrial pressure,[4] *and to the severity of the mitral stenosis* [5] *It might* be supposed, therefore, that the degree of right ventricular hypertrophy apparent in the cardiogram would be a good guide to the severity of the mitral stenosis Wood [2] noted that the degree of right ventricular hypertrophy was correlated closely with the height of the pulmonary arteriolar resistance, while Goodwin et al [5] found poor agreement between the degree of right ventricular dominance on the one hand and the size of the mitral valve or degree of pulmonary hypertension on the other, but Wood and Goodwin agreed that severe right ventricular dominance indicated a high pulmonary arterial pressure and resistance and a small mitral valve The association of augmented, pointed P waves without proportionate evidence of right ventricular dominance should suggest the possibility of associated tricuspid stenosis [6]

The difference in the findings in the *two* series of cases may be explained by several factors The electrocardiographic assessment of the severity of right ventricular dominance is difficult The degree of pulmonary hypertension was measured by cardiac catheterisation in Wood's cases, but for the great part it was assessed radiologically *in those of Goodwin et al Moreover,* associated left ventricular hypertrophy may modify the picture [7], Goodwin et al claimed that some patients with critically *stenosed valves had no evidence of any right ventricular* hypertrophy, and only a third of these had any left ventricular hypertrophy

Extreme right ventricular dominance is associated with tall delayed R waves, sometimes preceded by Q waves and followed by inverted T waves, in right precordial leads, and deep S waves in *left* precordial leads These findings are common in congenital heart disease, such as pulmonary stenosis, but rare in acquired right ventricular hypertrophy, including *that* accompanying mitral stenosis [8] Morris and Whitaker [9] reported 9 such cases in 173 patients with mitral stenosis, and Pruitt and Robinson [10] found 41 cases in 93 patients with severe mitral stenosis, and 53 of extreme right ventricular dominance among 147 patients with mitral valve disease of all types

The evidence therefore suggests that critical mitral stenosis (if not severe pulmonary arterial hypertension) can exist without a corresponding *degree of right ventri*cular dominance on the cardiogram The presence of gross right ventricular dominance in mitral valve disease virtually *guarantees severe pulmonary arterial* hypertension, but does not exclude mitral incompetence associated with stenosis [5] When there is cardiographic evidence of abnormal left ventricular dominance, pure mitral stenosis cannot be the sole lesion, and dominant mitral incompetence, aortic-valve disease, or severe systemic hypertension is likely

TUBULAR DYSFUNCTION IN NEPHROSIS

RENAL biopsy in the nephrotic syndrome has shown that among the common renal lesions are subacute glomerular nephritis (membranous or proliferative), chronic glomerular nephritis, diabetic glomerulosclerosis, lupus nephritis (in systemic lupus erythematosus), thrombosis of the renal vein, and renal amyloidosis [1] But of 56 cases investigated in this way, 6 are described as "nephrotic syndrome with predominant tubular degeneration" [1] This is interesting because it has become widely accepted that in the nephrotic syndrome the primary lesion is glomerular, causing increased filtration of protein, and that the heavy proteinuria is only partly or else not at all due to defective tubular reabsorption Such histological changes as are present in the proximal tubular epithelium are related by some to maximal protein reabsorption, and simple tests, such as measurement of specific gravity range or *p* aminohippurate excretion, show normal tubular function in most cases

The primary importance of a glomerular lesion in nephrosis has now been challenged, however, by Freeman and Joekes,[2] who believe that there is "diminished tubular protein reabsorption, without necessarily any abnormal escape of protein through the glomeruli" By means of paper electrophoresis they studied the differential protein patterns in serum, urine, and œdema fluid of 6 nephrotic patients The patterns were very similar in urine and œdema fluid, which both showed a much higher proportion of albumin to globulin than did the serum Freeman and Joekes reason that the abnormal quantities of plasma lipoprotein and the consequent increase in the molecular size of the globulins led to a preferential loss of albumin into the tissue spaces and renal tubules Normal or raised ratios of serum-albumin to tissue-fluid albumin in these patients appeared *to* exclude an increased escape of albumin due to a generalised capillary lesion These findings are of interest, but the argument put forward by Freeman and Joekes is by no means conclusive

Stanbury and Macaulay,[3] who accept the glomerular lesion as primary, have recently discussed secondary renal tubular insufficiency in the nephrotic syndrome Renal glycosuria and amino aciduria, either singly or together, have been reported in nephrotic patients, and Tegelaers and Tiddens [4] have described a more complex combination of tubular defects in 2 nephrotic children in whom renal glycosuria and amino aciduria, acidosis, hypokalæmia, and polyuria developed The rather similar patient described by Stanbury and Macaulay was first seen at the age of 2 years with all the typical clinical and biochemical features of the nephrotic state and was treated with *cortisone for a week,* concentrated plasma infusions, low salt and high-protein diet, and, for several months, cation-exchange resin ('Katonium') The nephrotic *state continued, but* hypocalcæmic tetany developed when the patient was 4 years of age, and subsequently he was found to have renal glycosuria and amino aciduria, which had not been present at the onset of his illness

---

2 Freeman, T Joekes A M *Acta med scand* 1957 157 43
3 Stanbury, S W, Macaulay, D *Quart J Med* 1957 26 7
4 Tegelaers W H Tiddens H W *Helv pædiat Acta*, 1955, 10, 269

Next he had a frank hypokalæmic episode, with muscle weakness and confusion Hypokalæmia had been detected biochemically, but had been disregarded, shortly after administration of cation-exchange resin had been discontinued At the age of 5 the child was dwarfed and showed delay in the appearance of centres of ossification and osteoporosis, probably due to extreme protein depletion and inadequate intestinal absorption of calcium , he still had heavy proteinuria and hypoproteinæmia, polyuria, glycosuria, amino-aciduria, potassium deficiency, and metabolic acidosis were present and were ascribed to defects of renal tubular reabsorption These tubular defects might have been due to persistence of severe tubular degeneration, such as is known to occur in acute membranous glomerular nephritis An alternative suggestion by Stanbury and Macaulay is that the cation-exchange resin brought about potassium deficiency and tubular kaliopenic nephropathy with possible irreversible damage However it was produced, the combination of tubular defects in this patient is reminiscent of that in cystine-storage disease (Lignac-Fanconi disease) and in a varied set of tubular nephropathies generally grouped under the unsatisfactory title of "adult Fanconi syndrome" Obviously, renal tubular deficiencies can arise singly or in many combinations and may be due to congenital defect of tubular structure or function or to a wide variety of acquired diseases, among which we may now have to include the nephrotic syndrome, or, possibly kaliopenic nephropathy resulting from its treatment

THIOBARBITURATES IN ANÆSTHESIA

The synthesis of the thiobarbiturates was described in 1935,[1] and a year later the first reports of the clinical use of one of them, thiopentone, began to appear Since then, thiopentone has remained the most popular intravenous anæsthetic But knowledge of its side-effects and of its mode of breakdown in the body has led to the introduction of other thiobarbiturates, and more recently of other drugs

The principal side-effects are depression of respiration and circulation, and increased liability in some patients to coughing and laryngeal spasm The relatively brief anæsthetic action of thiopentone was early claimed as a major advantage, but by modern standards it is too long in certain circumstances Moreover the speedy return of consciousness that follows its use is due not to quick detoxication, but to a rapid redistribution of the drug in the body Thus for about 30 hours after an induction dose of thiopentone, enough of the drug remains in the body to affect the duration of action of a subsequent dose[2] Too large an initial dose prolongs unconsciousness , even a small dose leaves the patient unfit for responsible action for some hours (though he may not be aware of it himself), and repetitive doses are cumulative

Other thiobarbiturates were first introduced primarily to circumvent the side-effects Clinical reports appeared in 1946 of thialbarbitone ('Kemithal'), synthesised in 1938, and in 1950 of thiamylal ('Surital'), one of the original thiobarbiturates Neither of these drugs is sufficiently different from thiopentone to have achieved widespread use as an alternative

Interest in recent years has been concentrated on duration of action rather than on side-effects and two other thiobarbiturates have achieved some prominence One—methitural sodium ('Neraval,' 'Thiogenal')—seems to differ little from thiopentone[3] Favourable reports on the other—buthalitone sodium ('Transithal' 'Ulbreval' 'Baytinal')—have appeared in this country and a much briefer effect than that of equipotent doses of thiopentone has been claimed for it[4] But clinical assessment of the duration of effect of these anæsthetics is difficult and more objective measurement by means of the electro encephalogram suggests that buthalitone may in fact be active for even longer than thiopentone, though the difference between the two is slight[5]

The best hope of better intravenous anæsthetics may lie in investigation of drugs other than thiobarbiturates Hydroxydione ('Viadril'), a steroid with anæsthetic potency, has some advantages,[6] and a new substance—5 ethyl-6-phenyl-meta-thiazone-2,4 dione ('Dolitrone')—has been synthesised and used clinically for intravenous anæsthesia, but without striking advantages[7]

PELVIC TUBERCULOSIS

Chemotherapy has transformed the prospects for women with tuberculous infection of the genital tract This is not a common disorder, but the increasing investigation of women with minor gynæcological disturbances is revealing an unexpectedly large proportion of cases of pelvic tuberculosis A frequency of 5 3% has been found among nearly 2000 patients complaining of infertility, and this figure is regarded as a minimal estimate[8] Other common presenting symptoms such as pain, abnormal uterine bleeding, amenorrhœa, and vaginal discharge have led to the discovery of this underlying disorder, often without any palpable abnormality in the pelvis. Pelvic tuberculosis must always be borne in mind as a potential cause of persistent gynæcological symptoms, especially when infertility coexists Halbrecht[9] found that 40% of cases of blocked fallopian tubes (discovered on salpingography for primary sterility) were caused by tuberculosis The diagnosis is usually made by histological study of the endometrium , the specimen should be obtained as late in the cycle as possible to give the slow-growing tuberculous focus as long as possible to develop (Fewer cases of endometrial tuberculosis would be missed if routine curettage was more commonly timed for the premenstrual phase)

Before the advent of chemotherapy it was perhaps of academic importance whether the early case was diagnosed, for treatment was restricted to general health measures, a sanatorium regime, or X-ray therapy to suppress ovarian activity and rest the genital tract[10] The extent of the change that has taken place is indicated by the final report of the joint subcommittee of the British Tuberculosis Association and the Royal College of Obstetricians and Gynæcologists on the treatment of endometrial tuberculosis with streptomycin and *p* aminosalicylic acid (P A S)[11] This report analyses the results of a controlled trial in several centres in England and Scotland from 1950 to 1952, in which women with tuberculosis limited to the genital tract were allocated at random to a treated or an untreated group and followed up according to a prearranged schedule The treated patients received a three month course of streptomycin (calcium chloride complex) 1 g and P A S 12 g daily as outpatients

Of 43 treated patients who were observed for a year from the start of treatment, only 5 showed bacteriological evidence of recurrence, whereas of 44 untreated cases 11 had to be removed from the trial because of clinical deterioration and given immediate treatment, and 25 of the remaining 33 still had evidence of tuberculosis at the end of a year

Unfortunately, after treatment infertility usually persists[3] By the time the diagnosis is made, the tubal epithelium has already been damaged, and successful pregnancy is all too rare [12] At present relief of infertility depends chiefly on prompt diagnosis and treatment Further studies are in progress to determine what combination of drugs gives the best results, and to probe deeper into the all-important time factor Comparison with practice in pulmonary tuberculosis suggests that longer courses of treatment may still further reduce the incidence of recurrence, and that P A S and isoniazid by mouth are less likely to have serious side effects or to cause the patient to default

Possibly in the future irreparable tubal fibrosis may be prevented by combining chemotherapy with cortisone or allied substances

QUARANTINE IN POLIOMYELITIS

THOUGH poliomyelitis is classed among the highly infectious diseases, secondary cases among family contacts are relatively uncommon In a statistical survey in this country, Spicer and McDonald,[13] using data obtained in the Medical Research Council's investigation of inoculation and paralysis, found that among 7782 households in which there was a primary case of paralytic poliomyelitis, in only 82 did another paralytic case follow They suggest that, as far as home contacts are concerned, quarantine and passive immunisation with gamma globulin have little value One course often followed in this country is to confine close child contacts to house and-garden quarantine for three weeks from the date of last possible exposure to infection, and to exclude *all* family contacts from school Only in exceptional circumstances are adults kept away from work [14] The W H O expert committee on poliomyelitis [15] recommended that "children with familial or intimate exposure should be confined to their homes for 21 days Adults need not be confined they should refrain from association with children other than their own and should avoid intimate contact with adults"

Strict quarantine measures, even if desirable, are not always practicable they need much organisation and take up a great deal of the public health department's time To be successful, they depend on the support of the public, and therefore on effective publicity and propaganda In a thickly populated area the task may be almost impossible, for one thing, interference with the work of the community may not justify the results achieved In a small isolated community, on the other hand, quarantine may be feasible and effective in stopping an outbreak [14], though Goffe and Parfitt [16] were not persuaded that quarantine measures did anything to stop community infection in the small winter outbreak they studied Agerholm,[17] however, was convinced of the value of quarantine she maintained [18] that the persistence of virus in the fæces was less important than many people supposed, and she believed that the real danger lay in pharyngeal carriage, which lasted for a much shorter period and would therefore be more susceptible to control by quarantine But not everyone is yet prepared to relegate the fæcal carrier to comparative insignificance

Further data about the influence of quarantine are therefore welcome, and the organisation and results of strict house quarantine in a housing estate in an isolated valley near Brighton have lately been described by Parker [19] Such elaborate measures had not been taken in the borough before, because, as is usual (and extremely likely in a town with a large floating population), the number of sporadic apparently unrelated cases did not seem to justify more than routine action But when 5 cases of paralytic poliomyelitis were notified in a week among children living on the estate, which had been free from the disease for at least five years, it was decided to impose house and garden segregation on everyone in the affected families This rule was relaxed only to allow the housewife to go shopping once a day, and she was instructed to wash her hands immediately before she went out Only 3 new cases were diagnosed on the estate later than twelve days after the diagnosis of the first case and four days after strict quarantine was begun 2 of these 3 cases were from houses already in quarantine In Brighton itself, however, sporadic cases continued to appear for more than two months There is no proof that quarantine protected the housing-estate from further attack, but the results are, to say the least, interesting

Public cooperation in the quarantine measures was sought in various ways A team was formed from members of the child welfare and school health services who were already familiar to those living on the estate The head teacher of the school "at once assumed the position of leader of the local population," and the school became the operational centre Public meetings were addressed by the medical officer of health, and the local press passed on information and advice [20] Those in charge appreciated that success depended on full public support It is noteworthy that, as a result of the crisis, barriers were broken down and a good community spirit sprang up where little had existed before

Experiments of this kind should be repeated elsewhere when conditions are favourable, and much valuable information could be gained by carrying out at the same time virus examination and antibody surveys in contacts and others (We refer on p 1305 to some preliminary details from a London borough where the fæces of contacts of a case of poliomyelitis have recently been examined) Good opportunities for such inquiries may present themselves in the next few weeks next year the picture may have been complicated by the immunisation of large numbers of children

BIRTHDAY HONOURS

THE barony accorded to Sir Horace Evans in the Birthday Honours list will give pleasure to the many colleagues who have observed his lightly borne wisdom in consultation and his cheering friendliness to all patients from king to commoner Mr Ralph Marnham, surgeon to St George's Hospital, London, is appointed K C V O for services to the Royal house Major General F K Norris, who is appointed K B E, is well known in Australia and beyond for his service in the Army, ranging from combatant duties in the 1914–18 war to the post of director general of medical services in 1948–55, and for many other useful activities Australia will also welcome the knighthood granted to Prof A B P Amies, dean of the faculty of dental science in Melbourne, who became known to a wider circle in the Western Desert in the late war Other doctors in the Commonwealth who are honoured include Mr J H Pierre, who has pioneered chest surgery in the West Indies, and who is now created a knight In this country knighthood is to be conferred on Prof G R Cameron, F R S, the author of distinguished work on cellular pathology, Dr R Brunel Hawes, who holds the important post of consulting physician to the Colonial Office at an exacting time, Prof G W Pickering, who, at his translation last year from London to the regius chair in Oxford, was already esteemed as a professor of medicine and as a person, and Colonel M Stoddart-Scott, M P, and Mr S T Irwin, M P, Northern Ireland, who are honoured for political and public services To these and others whose names appear on p 1295 we offer our congratulations

The Wider World

REFLECTIONS ON MEDICAL TRAVEL

L J Witts
D M Oxfd, M D Manc, Hon Sc D Dubl, F R C P
NUFFIELD PROFESSOR OF CLINICAL MEDICINE,
UNIVERSITY OF OXFORD

AIDED foreign travel, like the aeroplanes we travel in, is part of the post-war way of life It goes with egalitarianism and new types of privilege, with high taxation and income tax rebates, with notional half-days and study leave It is a product of the past decade and the time has perhaps come to review its development

How enjoyable was the first small international congress of internal medicine in Basle in 1946 and how sadly congresses have deteriorated since! Indeed, their initial success was largely due to the fact that they manifested a world set free, they satisfied a need, and they were spontaneous and improvised Today, congresses are immense in size and they are organised down to the smallest item There were 1500 hæmatologists at the last congress of the International Society of Hæmatology, which is a relatively small specialty, and the expenditure for the congress exceeded 100,000 dollars[1] The attendance at symposia on some minute facet of medicine may be numbered in hundreds

One thinks of the long period of gestation, the delay between the acceptance of a paper and its delivery, which means that the material is already out of date by the time it is given, the concessions to international susceptibilities in the choice of programme, the ageing stage army of regular performers, the frequently deplorable level of presentation, the devitalised version of the addresses that comes over the Tannoy, the impossibility of discussion, the host of papers read by title so that participants can obtain currency allowances and tax reliefs, the inability to see one's friends unless one arranges a rendezvous beforehand, the banquets with the conventional references to the internationality of science, the expensive outings and the crowded sightseeing—and one wonders sadly whether medicine, too, has not come under the sway of Admass

Congresses have become too large and too frequent if their object is the advancement of medicine and the promotion of friendship among physicians The cost per head rises steeply when the attendance exceeds a few hundred, and the organisers become preoccupied with the physical problems of the meetings, the organisation of entertainments and the collection of subventions from the pharmaceutical and other industries However, the main subject of my paper is not these *omnium gatherums* but the growing stream of individuals who journey from our shores to all parts of the earth as visiting professors, lecturers, examiners, advisers, and so on This, again, is a new phenomenon Few, if any, of my teachers in Manchester and Cambridge, and few of my pre war colleagues on the staffs of London hospitals, had ever visited one of the Dominions or Colonies in peace time, and that indefatigable traveller, Sir Arthur Hurst, did not get farther than North America

Whereas international medical conferences might well be diminished in size and frequency, I believe that the more solitary migrants have an increasingly important part to play in the development of medicine and in the enhancement of England's status in the comity of nations Because aided travel is new, it is probably susceptible to technical improvement, and this must be my excuse for some notes on a term of absence in which I travelled around the world in 130 days A little mathematics shows that the average velocity was over 200 miles a day and the circumspection therefore somewhat superficial The journey is seen, however, against the background of previous trips to Europe and America

* * *

The human brain, particularly at the age when visiting professors are selected, is not a high-speed camera, and impressions soon blur if they are received in too rapid succession I believe a process of unconscious re remembering has to go on for some time until an imprint on the brain is fully developed This seems not to happen if the attention is closely focused on ever changing scenes, and the traveller should remember Wordsworth's dictum that emotion must be recollected in tranquillity if it is to issue again in a communicable form It is wise, therefore, to insist on a five day week, with one week out of every five off all duties, including social duties Moreover, it is foolish to travel round the world and to miss seeing the Barrier Reef, Alice Springs, Darjeeling, and the Khyber Pass In retrospect, the journeys along the interminable corridors and stairs of so many departments of anatomy and pathology have faded into a grey cloud, whereas a sunny afternoon at the races in Sydney, or a dinner by candlelight at the club in Melbourne, remains indelibly fixed in the mind "Not by eastern windows only, when daylight comes, comes in the light"

* * *

There are three types of academic foreign travel, the visit, the progress, and the sortie They are not mutually exclusive and in this recent trip a visit and a progress were combined The most profitable period, for others as well as myself, was the five weeks I spent in Sydney as McIlrath guest professor There we stayed in one place —actually in the hospital—long enough to get to know well the staff, the students, and in particular the hospital residents I was in charge of beds and took part in teaching, including the postgraduate fortnight, so that there was no need to collect special audiences, as sometimes has to be done for a visiting lecturer I had the opportunity to go out to near by centres such as Canberra and Orange, to visit practitioners in their homes and cottage hospitals, and to become familiar with the general social and economic background

The rest of our trip was what I have called a progress Here, to change the metaphor, one starts on a conveyor belt under the ægis of a sponsoring organisation, and the belt moves inexorably along Life is a succession of academic and social engagements and unrestful travel, and six weeks of this in Russia is said to destroy one's taste for caviare and champagne for the rest of one's life If you have a queazy stomach your travel will be one long dyspepsia, and, if you have not, you will increase your chances of bronchial carcinoma and coronary thrombosis, which have taken a heavy toll of recent medical travellers You are introduced as an expert in some small sector of medicine, and if you are a hæmatologist the same obscure cases of aplastic or hæmolytic anæmia, of lymphadenopathy, or leukæmia turn up wherever you go A longer stay is necessary to convince people that you are interested in medicine as a whole

The worst method of travel is the sortie, in which the holder of a travelling professorship, instead of taking long leave of absence, continues to look after his firm, his practice, or his department and makes brief dashes across the oceans like a water-beetle zigzagging across a pond This indicates a misguided sense of personal indispensability Any well established department should be able to spin for some months like a humming top without further application of the whip It is true that the current quip has it that the part time consultants are away part of the time and the whole time consultants away the whole of the time It is true, too, that some travellers return home to find that their subordinates have become dissident, but these are usually men like Richard I, for whom foreign excursions have become a perpetual way of life The ordinary man who cares for his personal work and therefore travels only at reasonable intervals is well advised to delegate his duties entirely and not try to fill two exhausting rôles at the same time

---

[1] *Blood* 1957, 12 96

Short visits do, of course, have their rewards, for one makes many friends and receives abundant hospitality Centres which are often by-passed may be greatly stimulated by a visit and immensely grateful for the contact While, therefore, it is bad for a single individual to make a journey which consists of short visits to many different places, it would be good to try to satisfy the desire for more contacts with English medicine by encouraging more people to interrupt the flight to Australia or the Far East and to touch down and lecture at one centre at least A continuous flight to the Antipodes is exhausting if it is not interrupted by one or more breaks en route Again, it would be better for a Sims professor to spend six weeks at two of the six capital cities in Australia rather than two weeks at each of them Over the years it could be ensured that each capital city got a fair proportion of the professors'

* * *

A visit may be of any length, though anything more than the traditional sabbatical year would be unusual What I have termed the progress, where the visitor is travelling more or less continuously, should probably not be less than three weeks, to justify the expense of the journey, nor more than three months, to maintain peak performance In many people the return home is followed by a period of reactive depression which has been called the repatriation syndrome Some of the components of this are fatigue, the accumulation of tasks and problems during absence, and the switching-off of the limelight in which the traveller has basked so happily

* * *

A difficulty with a lecture tour through a variety of countries is the different character of the audiences which are encountered The same lectures will not be suitable for all of them With the growth of medical travel and writing, ideas travel quickly and modern audiences have become like the ancient Athenians who perpetually demanded some new thing It is idle to pretend that any of us possesses a large stock of unpublished information, and the preparation of a great number of lectures summarising current knowledge is a wearisome task

In the large centres in Australasia the doctors are right up to date and they complain that some recent visitors have talked down to them They require something sophisticated, with an element of personal research The men in the smaller centres in Australia are equally up to date, but they want something of a practical type which deals with the current problems of Western medicine In India and the Far East the medical setting is quite different It is important to note that the major problems are not those of tropical medicine in the accepted sense, in so far as they are, they can be left to experts in tropical medicine Most of the clinical material is identical with what Osler saw and described in North America over seventy years ago, but it is on a vast scale, it has to be handled on a doctor-patient ratio of 1 to 10,000, and it is presented against the background of modern chemotherapy and modern ideas about public health For example, all these Eastern countries are going through an epidemic of tuberculosis which is more severe than the one we experienced in Europe a hundred years ago, but today much more is known about the epidemiology and treatment of tuberculosis

Other common illnesses are nephritis, rheumatic heart-disease, and rheumatoid arthritis, anæmia and leukæmia, jaundice, cirrhosis of the liver, and splenic anæmia, bronchitis, emphysema, and heart failure, typhoid and the dysenteries Some diseases which are important in this country, such as pernicious anæmia, ulcerative colitis, and disseminated sclerosis, are almost completely absent, and there is little interest in geriatrics when half the population is under the age of 21 There are, of course, regional differences, lung cancer and peptic ulcer being common in Burma but uncommon in North India and Pakistan

The problem in the East is to smash these great epidemics of disease and to discover the best way of doing this with limited man-power and funds Expensive individual procedures—what I call millionaire medicine—are of much less practical importance than community programmes, and therefore lectures on field work, screening for disease by simple tests and therapeutic trials, should be successful, even though British experience is not immediately transferable This is not to say, of course, that the physician in the East does not enjoy the occasional purely scientific lecture as much as the physician in the West and there is always interest in material which can be presented dramatically or visually, such as plastic surgery, cardiac surgery, and thoracic surgery

(To be concluded)

Occasional Survey

THE ARCHITECTURAL FUNCTION OF PULMONARY CAPILLARIES

R E Bonham Carter
M B Camb, F R C P
PHYSICIAN, UNIVERSITY COLLEGE HOSPITAL, AND THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET, LONDON

RESEARCH has suddenly advanced our knowledge of the initial expansion of human lung The idea that the lungs first expand gradually over hours or days was never held by Potter,[1] who showed that inflation with either air or oxygen caused irregular expansion, with distension of the proximal parts of the lung and atelectasis of the distal parts She also showed that this histological appearance in the mature neonate proved that an attempt had been made at resuscitation by inflation In premature neonates weighing 1000–2000 g Potter found the same appearance produced by the infants' own respiratory efforts Lind and Wegelius,[2] in their exquisite ciné radiological studies, show how quickly the lungs expand in normal neonates with the first two or three breaths the lungs expand "like the lighting of a lamp," and the heart, which is initially large, diminishes stepwise with each respiration

Jaykkä [3] has shown that the extirpated lungs of full-term neonates cannot be fully expanded by the air-pressure difference resulting from a negative pressure of −20 cm of water applied outside the lung in a partially exhausted jar and a positive pressure of + 20 cm of water applied within the trachea This experiment produces a histological appearance similar to that shown by Potter [1] to be typical of the lungs of mature neonates in whom inflation by air or by oxygen had been tried as a means of resuscitation

More important is Jäykkä's finding that when a fluid pressure of 80 mm Hg is put into the pulmonary artery in addition to the above mentioned application of the air-pressure difference, the alveoli expand to their proper extent He considers that the pulmonary capillaries are erectile and help to hold out alveoli as a result of their distension with blood His inability to expand the lungs of fœtuses weighing 500–800 g by this method he explains on the grounds of immaturity of this erectile capillary system

---

[1] Potter E L Pathology of the Fetus and the Newborn *Chicago*, 1952
[2] Lind J Wegelius C *Int Cong Pædiat* 1956
[3] Jäykkä S *Acta pædiat, Stockh* 1957, 46, suppl 112

Dawes et al [4] and Born et al [5] have shown in lambs that, before the lungs expand, the initial pulmonary vascular resistance is high and can be made higher by asphyxia produced by tying the cord before the onset of respiration The fact that the pulmonary resistance can be varied by asphyxia implies an ability on the part of this vasculature, probably the arterioles, to contract and so to raise the resistance and to impede the onward flow of blood to the capillaries

Bonham Carter et al [6] seem to have shown that a high venous pressure, measured in the inferior vena cava, is beneficial to premature neonates with respiratory difficulty at or shortly after birth, and these workers suggest that this benefit is derived from a high cardiac output (stroke volume) dependent on a high venous pressure

The foregoing work seems to show two things

(1) Initially the alveoli are expanded by the erectile pulmonary capillaries and the air pressure difference created by respiratory effort

(2) Where the peripheral pulmonary vascular resistance is very high, probably made so by asphyxia, a high cardiac output is necessary to overcome it, so that the pulmonary capillaries may be adequately filled with blood and play their part in the proper expansion of the alveoli

Gunther [7] shows how much the position of the placenta relative to the baby and other factors, with the cord intact, can vary the neonatal blood volume—up to 47% of the expected total She also shows how, with the cord intact, the baby acts as a plethysmograph, recording, by increases in weight, the effects of uterine contractions on the placenta during the third stage of labour Sharpey-Schafer and Wallace [8] have shown, in adults, what a great volume of fluid is required to raise the systemic venous pressure by transfusion, and how fast it has to be injected, but Gunther's findings indicate a fast transfusion of a relatively great volume of blood during the third stage of labour under certain conditions

From the visible evidence of Lind and Wegelius's film of the stepwise diminution in the size of the heart during the first two or three breaths and from Bonham Carter's work it looks as though the stroke volume of the heart during the onset of respiration is high, and that the capacity of the neonatal right auricle to withstand a high pressure must be great, for a caval pressure of 14 cm of 5% dextrose solution in water has been recorded with survival It seems likely also that the factors described by Gunther play a part in the production of this high stroke volume Perhaps Starling's law is being exercised at the time almost at the maximal stretch of cardiac muscle

The redirection of blood with the onset of respiration must be considered A high right-auricular pressure must tend to keep open the foramen ovale because of its anatomical structure Therefore, unless there is a high left-auricular pressure, the right to left shunt must persist Could the initial distension of the heart seen in the radiographic film, and implied by Gunther's work, provide for this shunt and for adequate right ventricular filling? Or must a sudden rise in left-auricular pressure be assumed? If the left auricular pressure rises thus, as well it may, as the result of the high right-auricular pressure and the foramen ovale shunt, a "backward" distension of pulmonary capillaries may occur (see below)

Barcroft [9] showed that the closure of the ductus arteriosus in lambs was related to the onset of respiration, probably by a mechanism involving an increase in systemic oxygen tension Lind [10] and Hultgren [11] have produced evidence that the duct can be reopened, in human neonates, by interference with respiration or by breathing low-tension oxygen It looks as though the duct closes with normal oxygen tensions and reopens or remains open with anoxia If the peripheral pulmonary vascular resistance is high, the pulmonary artery pressure will also be high, if the cardiac output is maintained Asphyxia if this produces the same effect in men as in lambs, will do this However, the direction of the flow in patent ductus arteriosus will depend on the relative pressures in the systemic and pulmonary circuits, if the flow is largely from pulmonary artery to aorta, the blood normally used to distend pulmonary capillaries will be diverted conversely, if the flow is the other way, the erection of pulmonary capillaries will be assisted by the shunt from the aorta

This conception of the architectural function of pulmonary capillaries and the part they play in the initial expansion of human lungs can be related to the clinical picture of neonates with difficulty in breathing—what Bound et al [12] called "the pulmonary syndrome of the newborn" These infants at, or shortly after, birth make desperate respiratory efforts They have episternal, lower costal, and even sternal recession, and yet achieve little or no ventilation They are commonly premature and born by cæsarean section The physiological explanation of this behaviour may be that of a premature infant rendered asphyxial by some accident of birth, with the result that the peripheral vascular resistance in his lungs rises with increasing asphyxia in a vicious spiral, until his cardiac output cannot overcome it, so his alveoli are never properly expanded Possibly this situation arises from, or is aggravated by, a blood volume diminished by the factors shown by Gunther and possibly by early tying of the cord

To explain on this hypothesis the ability of neonates with pulmonary atresia or with severe pulmonary stenosis to expand their lungs is difficult, unless the ductus arteriosus temporarily remains patent with a shunt from aorta to pulmonary artery and possibly with minimal assistance from the bronchial arteries Such infants, however, would remain anoxic and so might be expected to maintain the patency of the duct

If this hypothesis is acceptable, and the structural function of the pulmonary capillaries is maintained in later life, other concepts may follow Lung elasticity (rigidity), its ability to relax from the inspiratory phase, will in part be a function of pulmonary capillary pressure

Taussig [13] has drawn attention to the fact that children with congenital heart-disease and large left to right shunts have large lungs, a bowed sternum, and a flat diaphragm, and this has been our constant observation in the congenital-heart clinic at Great Ormond Street A large left-to-right shunt will result in overdistension of the pulmonary capillaries until or unless the peripheral vascular resistance increases sufficiently to reduce the blood-flow This, in a manner of speaking, is the "forward" form of pulmonary capillary distension giving rise to an inability of the alveoli to relax completely The measurement of residual air is impossible in little children, but we have found, by way of indirect evidence, a tendency in such cases without congestive failure to retain carbon dioxide with a shift of blood pH to the acid side, as if the mixture of gases was imperfect (unpublished data)

Hellems et al[14] and Lagerlof and Werko[15] have shown how pulmonary capillary pressure reflects the pressure in the left auricle So a "backward" form of overdistension of pulmonary capillaries could arise from changes in left auricular pressure with similar effects on the alveoli The clinical picture here is that of cardiac asthma with its expiratory wheeze Christie and Meakins[16] and others since have shown that an increase in residual air is usual in patients with chronic congestive cardiac failure, and an inability of the alveoli fully to relax in expiration may be the cause

Finally, it must be said, that although *pressure, flow, and resistance in the pulmonary circuit* are interrelated according to Ohm's law and will therefore affect the rigidity and flaccidity of the capillary network, the property which is most responsible for this will be the tension in the wall of the capillaries This tension, as in a tyre, will be related not only to the pressure within the tube but also to the radius and diameter of the tube Under static circumstances this relationship can be expressed thus

$$\text{Tension} = \frac{\text{pressure} \times \text{radius}}{2}$$

So little of the original work on this subject is mine that I clearly owe a debt to all those whose writings I have read on this subject, and all the friends that I have bored with it, particularly John Bound, Mavis Gunther, and Jean Smellie of the Obstetric Hospital, U C H

AN ATTEMPT TO COUNTER "INSTITUTIONALISATION" IN CHRONIC SCHIZOPHRENIC PATIENTS *

A R MAY
M B Lond, D P M
ASSISTANT PSYCHIATRIST,
NETHERNE HOSPITAL, COULSDON, SURREY

HABIT TRAINING is now a recognised method of dealing with the chronic deteriorated patient in a mental hospital As its name implies, it seeks to impose socially acceptable behaviour on the patient by a process of conditioning But though the patient's behaviour improves, he remains "institutionalised"[1], for the method is disciplinarian and does not sufficiently encourage the spontaneous development of social interaction and initiative Our experience among these patients led us to consider how we could counter the automatic pattern produced by conventional habit-training programmes

In 1955 and 1956 I was concerned with a male ward[2] and a female ward[3] of chronic deteriorated patients By habit-training we were able to improve their behaviour and to open both wards within a year Aggressive behaviour remained the greatest difficulty, but we noticed that at mixed parties of patients from both wards there were hardly any acts of aggression and that the spontaneity and interest of patients improved

This observation prompted us to consider extending this social contact by creating a mixed unit for deteriorated patients Our aims were roughly defined as investigation of the effect of community life on the behaviour and psychotic process of deteriorated schizophrenic patients, and the effect of this new therapeutic policy on the attitudes and beliefs of all the staff By treating this as a pilot study, we hoped to get some idea of the difficulties which would arise when extending this mixing of the sexes to other parts of the hospital

A Schizophrenic Community

At the outset we decided to make our intentions as widely known as possible to all grades of staff The first plans were made in September, 1956, at meetings with ward and administrative nursing and medical staff In general there was considerable enthusiasm among those directly concerned, but misgiving among those who distrusted the disturbance of the traditional dichotomy between male and female sections of both patients and staff Others saw it as yet another innovation which would upset the comfortable equilibrium of institutional life But after discussion it was eventually agreed to give the plan a trial In November, 1956, 44 men and 43 women patients were transferred from their wards to two adjacent villas in the hospital grounds

Patients

The criteria for selection of these patients were a diagnosis of schizophrenia, a history of treatment in a mental hospital for five years or more, and a maximum age of 50 Further details about them are given below

	Men	*Women*
No of patients	44	43
Average age	40 4 yr (range 26–50)	37 4 yr (range 20–50)
Average time in mental hospitals	14 3 yr (range 5–37)	12 3 yr (range 5–21)
No of patients who have had		
E C T	39	43
Deep insulin	7	14
Leucotomy	7	17

All patients had been rated on the Fergus Falls behaviour-rating scale by at least two independent raters before they were moved The senior ward staff had been with them for a year or more and knew them well

Pattern of Care

The actual move was made with the minimum of disturbance The villas are surrounded by a large railed garden, and for the first two weeks the gates were closed in case patients wandered away Thereafter they were opened, and they have remained open ever since The doors of the villas were opened from the start

The mixing of patients was at first allowed to develop spontaneously After four days a woman wandered into the male villa and was promptly handed a bucket and scrubbing-brush, she scrubbed the kitchen floor without protest, but has never done as well since In the first week about a dozen men and women patients began to meet inside and outside the villas

In the second week a more formal programme was started From both sets of patients were drawn two groups of 12 each, under one nurse The sister or charge nurse was responsible for the remaining larger group, some of whom were better preserved ward workers We were obliged to accept these unsatisfactorily large groups because we had so few nurses Nurses in charge of groups understood that they were expected to organise the social and working activities of their group as well as getting to know all the members From the start it was made clear that rigid adherence to the programme was not expected—more important was the opportunity for mixing given by the programme

Men and women share gardening work on most mornings, and an art class for half of each villa is supervised by the art master twice a week A mixed "movement

with music" class is held one evening a week, and a ward social, with dancing and games, on another evening Both villas attend dances, concerts, and the cinema in the main hall Men and women who prefer to do so may watch television in the male villa in the evenings

If the weather is bad, there is always a group of men patients in the female villa and vice versa—where they are encouraged to share in simple occupational tasks

About three weeks after the move, one of the men patients visited the female villa and stayed to lunch He was well tolerated, and we decided to have mixed meals at separate tables We started with lunch and extended this to tea, behaviour at meals is excellent and there is virtually no disturbance, in sharp contrast to conditions in the original women's ward

Staff

The most fascinating and probably the most important aspect of all these developments has been the change in the attitude of the staff I hold a meeting with the ward-staff once a week, and once a month we have a larger conference with the medical superintendent, matron, and representatives from the administrative and training staff We keep a record of matters discussed at all these meetings, and they have developed into very lively affairs, with a refreshing lack of reserve Perhaps the best commentary on their success, or at any rate on their entertainment value, is the fact that although they started as lunch-hour sessions from 1 P M till 1 45 P M, we are now usually obliged to end them forcibly about 3 P M

The interaction between men and women staff, with mutual criticism, has changed our discussions out of all resemblance to the rather moribund meetings we used to hold on the separate male and female wards These discussions have been essential The gradual development of policy has been anything but smooth, and the unit has been the cynosure of the hospital as a whole The smaller ward staff meetings have been frankly therapeutic, and the attitudes expressed over the management of individual patients have been related to personal motivations, with a good deal of interpretation It has been most instructive to correlate the level of ward tension with the personal satisfaction or anxiety of the nurses

A major theme which has run through all these meetings has been the conviction of the female staff that the women patients are more active, more aggressive, and more difficult to manage than the apparently well-drilled or well trained men, and the equally strong conviction of the male staff that the women are not properly managed by the female nurses This is mainly because the men, who had followed a habit training regime for at least two years longer than the women, will *work* much better, though they are less spontaneous at social functions, and because the women are, by and large, as putty in the hands of the male staff But this rivalry seems to be gradually lessening

Response of Patients

Ten weeks after the move all patients were again rated on the Fergus Falls scale There was a strong positive correlation between these ratings and independent clinical assessments, but the scale is not precise enough to measure the more subtle alterations in social attitudes and group interaction which we have noticed

Though there has been no deterioration in the behaviour ratings since the move, neither has there been any significant improvement On the other hand, many patients have become more spontaneous in social situations, and disturbances in the ward have been noticeably reduced under the mixed regime Only 5 women, and none of the men, now require regular electroconvulsion therapy It has only been necessary to seclude 1 patient, a man who became disturbed by the presence of women patients and staff and eventually had to be transferred He was the sole casualty among the men 2 of the women patients had to be transferred, 1 because of persistent absconding, and 1 because she became disturbed and deluded as a result of the co education

The apathy which is the stigma of the institutionalised patient has almost disappeared The increased mobility and spontaneity is shown by the growing ease with which patients can be encouraged to perform fairly responsible tasks Most of the men can now be trusted to shave themselves, and many of the women can be sent on errands to the hospital shop The general bearing of patients has improved, they move more flexibly and with more purpose, and they can manage with less supervision than before Less time is spent on washing, dressing, and toileting All but about half a dozen will now answer when spoken to Some who were previously uninterested now speak of each other and the staff by name, and the isolating anonymity of ward life is partially dissolving

Conclusion

The experience of our first three months supports the view that change of environment towards a more normal community can have a therapeutic effect on chronic schizophrenic patients and can do much to combat institutional behaviour

The future development of this project depends on the staff, and therapeutic policy has now been directed to countering institutional attitudes in them, for only by some such reorientation can they (including the doctor) prevent the patient from sinking back once again into the amorphous mass of chronic schizophrenics

I wish to acknowledge the encouragement of Dr R K Freudenberg, physician superintendent, and to record my thanks for the cooperation and support of the nurses engaged in this project

BIRTHDAY HONOURS

THE list of honours published on June 13 contains the names of the following members of the medical profession

Baron

Sir HORACE EVANS, G C V O, M D Lond, F R C P
Physician to H M The Queen, physician to The London Hospital

K C V O

RALPH MARNHAM, M CHIR Camb, F R C S

K B E

Major General FRANK KINGSLEY NORRIS, C B, C B E, D S O, E D, M D Melb
For services to medicine

Knights Bachelor

ARTHUR BARTON PILGRIM AMIES, C M G, D D SC Melb, F.R A C S, F R C S F
Dean of the faculty of dental science, University of Melbourne

GORDON ROY CAMERON, M B, D SC Melb, F R C P, F.R S
Professor of morbid anatomy in the University of London at University College Hospital Medical School

RICHARD BRUNEL HAWES, C M G, M B Lond, F R C P
Consulting physician to the Colonial Office

SAMUEL THOMPSON IRWIN, C B E, M CH Belf, F R C S E, M P Northern Ireland
Consulting surgeon, Royal Victoria Hospital, Belfast, for political and public services

GEORGE WHITE PICKERING, M D Camb, F R C P
Regius professor of medicine, University of Oxford

Joseph Henry Pierre, M B Lond, F R C S E
Specialist surgeon, General Hospital, Port of Spain, Trinidad

Colonel Malcolm Stoddart Scott, O B E, T D, M D Leeds, M P
For political and public services

C B (Military)

Surgeon Rear Admiral David Duncan, O B E, M D Aberd

Major General Philip Francis Palmer, O B E, M B Dubl

Surgeon Rear-Admiral Arnold Ashworth Pomfret, O B E, M B Manc

C M G

Frederick Roland George Heaf, M D Camb, F R C P
David Davies professor of tuberculosis, University of Wales, consultant in tuberculosis to the Colonial Office

David James Masterton Mackenzie, O B E, M B Edin
Director of medical services, Northern Region, Nigeria

C B E (Military)

Air Commodore James Hill, M B Glasg, R A F

C B E (Civil)

Archibald Simpson Anderson, M B Melb, F R A C S
Honorary consultant ophthalmic surgeon, Victorian Eye and Ear Hospital, Melbourne

Alexander King Bowman, M B Glasg, F R F P S
Senior administrative medical officer, Western Regional Hospital Board, Scotland

David Paton Cuthbertson, M D, D SC Glasg
Director, Rowett Research Institute, Bucksburn, Aberdeenshire

Benjamin Thomas Edye, CH M Sydney, F R C S
Honorary consulting surgeon, Royal Prince Alfred Hospital, Sydney

Sybil Gertrude Horner, M B Lond
Senior Medical Inspector of Factories, designate, Ministry of Labour and National Service

Donald Hunter, M D Lond, F R C P
Physician and director of the department for research in industrial medicine (Medical Research Council), London Hospital

Samuel Horton Oluwolé Jones, O B E, M B Manc
Director of medical services, Gambia

Edmund Oliver Lewis, M A Camb, D SC Lond, M R C S
Lord Chancellor's Medical Visitor in Lunacy

Ernest Steven Monteiro, M D Malaya, F R C P
Dean of the faculty of medicine and professor of clinical medicine, University of Malaya

M V O (*4th Class*)

Surgeon Commander Peter Geoffrey Burgess, B M Oxfd, R N

William Neil Maclay, M B E, B A Camb, M R C S

O B E (Military)

Squadron-Leader Peter Howard, M B Lond, R A F

Surgeon Commander James Lees, M R C S, R N

Lieut Colonel Alexander Robert Taylor Lundie, M C, M B St And, R A M C

Lieut Colonel Walter William McLellan, R A A M C

Lieut Colonel Maurice Irving Silverton, T D, M R C S, R A M C, T A

Squadron-Leader Arthur John Wainwright, M B Birm, R A F

O B E (Civil)

Joseph Antoine Hermann Andre, M B E, M R C S
Deputy director of medical services, Mauritius

Thomas James Biggs, M B Sydney
Senior physician, Mater Misericordiae Hospital Sydney

Humphrey Malomo Samuel Boardman, L R C P E
Assistant director of medical services, Sierra Leone

Archibald Turner Macleod Blair, M B N Z
A medical practitioner at the Queen Elizabeth Hospital, Rotorua, New Zealand

Mabel Alice Dobbin Crawford, M D Dubl, F R C S I
Medical officer, Ministry of Supply

Alfred John Craig, M D Malta, F R C S
Professor of surgery, Royal University, Malta, senior surgeon, government hospitals

Muthiah Doraisingham, L M
Deputy permanent secretary to the Ministry of Health and deputy director of medical services, Singapore

Mary Katherine Dorothy Douglas, M B Edin
For political and public services in Fife

John Richard Hertslet Fulton, M B N Z, M R C P E
Chairman of the Otago hospital board, Dunedin

Noel Gerald Carleton Gane, F R C S E
Consultant surgeon, Salisbury Hospital and Rhodesian Forces

John Mark, M B
Medical practitioner and surgeon, Tauranga, New Zealand

Otto Mastbaum, M D Cologne
Malaria medical officer, Swaziland medical service

Frederick Lubovius Richard, M B Glasg
Commissioner, St John Ambulance Brigade, Staffordshire

Thomas Haines Sims, M B Camb
Senior medical officer, Ministry of Pensions and National Insurance

Robert Stewart Slessor, M B Aberd
Senior medical officer, Falkland Islands

Arthur Wesly Sugunaratnam Thevathasan, M R C P
For public services in Singapore

William Wood, M B Durh
Head of virus research unit, Glaxo Laboratories

M B E (Military)

Squadron Leader Irwyn Morse Perkins, M R C S, R A F

M B E (Civil)

Frederick Esibi, M R C S
For medical services in the Western Region Nigeria

Frank Neville Grannum, E D, M B Edin
Lately senior medical officer of health, Barbados

Thomas Patrick Howkins, M R C S
Divisional medical officer, southern region, British Railways

Ivan Saja Kadama
Medical officer, Uganda

Manchersha Manekji Kutar, M B Bombay
Assistant medical officer, Aden

Petro Solomon Blandina Muganwa
Medical Officer, Uganda

Vilikesa Ramaqa
Senior assistant medical practitioner, medical department, Fiji

Medicine and the Law

Dispensing Doctor Issues Prescriptions

The Minister of Health is to withhold £1100 from the remuneration of a doctor because of a breach of the regulations.[1] It was alleged that, between June, 1955, and March, 1956, he had issued prescriptions to the value of £269 16*s* 11*d* to patients for whom he was receiving drug capitation fees In some cases the names could not be traced as National Health Service patients, in others the names were indecipherable Some of the forms had been issued by the doctor's partners The Kent and Canterbury executive council had at first recommended that £500 be withheld, but on considering events before June, 1955, recommended withholding £1500 The Minister has decided on £1100 The doctor has accepted responsibility, but attributed the discrepancies to "muddle and not wilfulness"

---

[1] *Times,* June 13

Conferences

A TRUCE IN THE REMUNERATION DISPUTE

Special Representative Meeting of B M.A

A SPECIAL representative meeting of the British Medical Association decided on June 12 that the profession should give evidence to the Royal Commission and that a decision on withdrawal from the National Health Service should be deferred Dr SOLOMON WAND, chairman of the B.M.A council, summed up the situation by saying that a truce had been declared—an armed truce The profession's dispute with the Government remained unresolved and if it was not settled in a way that doctors could accept, then they must still be prepared to take vigorous action The breathing space, Dr Wand added, would give them an opportunity to strengthen finances and promote unity The need was for reunification, not recrimination

THE ROYAL COMMISSION

Early in the meeting, a representative suggested that everyone's minds were made up and that no arguments would change them Nevertheless, Dr G S R LITTLE (Greenwich and Deptford) pleaded forcefully for non-coöperation with the Royal Commission First thoughts he declared, were best and the first thoughts of the council had been not to give evidence to the Commission Whether the Spens reports were legally valid or not was unimportant Spens was not, as had been suggested, "in the melting-pot" it was in the incinerator Dr Little was sure that the Royal Commission would produce something much less attractive than Spens When the Commission had reported, the Government would accept only those recommendations which it was prepared to accept *now*

Dr C P WALLACE (Guildford) sadly reflected that, by reason of default, it had become inevitable to give evidence, and Dr A V RUSSELL (Wolverhampton) thought that, though the profession would not get very far by going to the Commission, there was now no alternative Mr H H LANGSTON (Winchester) was for a more cheerful approach ' if we are to give evidence, do not let us do so in this lukewarm way" But Dr C R G BARRINGTON (Bromley) saw little hope no other profession, he said, would put up with the treatment the doctors had received To give evidence to the Royal Commission was another step down the ladder and towards the state of mind in which " we do exactly what we're told "

PUBLIC-HEALTH DOCTORS

Anxiety about the future of doctors in the public health service found expression in an amendment declaring that evidence should be given to the Commission provided that either (*a*) all doctors in the public health service be included within the scope of the terms of reference of the Commission or (*b*) that an undertaking be given by the Government that an independent inquiry into the remuneration and status of all public-health medical officers be set up immediately Dr J A STIRLING recalled the view recently endorsed by the council of the B M.A —that coöperation with the Royal Commission should depend on the inclusion of public health doctors, and Dr J S G BURNETT spoke of the difficulties which faced those doctors in a service in which no cognisance was taken as far as remuneration was concerned, of postgraduate training and in which it was hard for doctors to get in the forty years' service necessary for full pension rights The meeting was clearly anxious to strengthen the position of colleagues in the public-health service but many representatives felt as did Dr A BROWN (Cambridge), that if they went on attaching impossible strings to the giving of evidence, they would do the public-health doctors a disservice

Dr J B TILLEY (Newcastle upon Tyne), chairman of the B M.A 's public health committee, said that they had tried hard to get the Minister of Health or the chairman of the Royal Commission to take one of these courses But not a shadow of a promise could be extracted The public-health committee had decided to leave the decision to the special representative meeting Dr WAND observed that general practitioners and hospital staff were in dispute with the Government the public-health doctors' dispute was primarily with local authorities The evidence of doctors in the public-health service would be presented to the Royal Commission, and this amendment would defeat the intention to give evidence Dr Wand could see no reason why the profession should not give evidence so long as their rights to seek fulfilment of the Government's moral obligations were not prejudiced By a large majority the meeting agreed that "the Association should give evidence to the Royal Commission on the understanding that it is given without prejudice to the profession's right to press for fulfilment of the Government's moral obligations inherent in the public and private assurances given by it and its predecessors to doctors taking part in the National Health Service '

WITHDRAWAL

This decision having been taken, there was no long debate on the issues concerning withdrawal from the National Health Service The meeting agreed to defer a decision on withdrawal, but the emphasis was on preparedness, and representatives insisted that the machinery and method of withdrawal be kept under constant review and that the council should also proceed urgently with preparations for an alternative health service

LEGAL ACTION ?

The possibility of taking action to test the validity of the Spens report as a legal contract for general practitioners again roused interest, as it had done at the special representative meeting on May 1[1] Dr WAND said that legal advice was firmly against such a course, and when some representatives seemed dissatisfied, he spoke more fully on counsels' views Dr I D GRANT, the chairman, ruled that this part of the discussion be private

Dr B BURNS (Sheffield) attributed this reluctance to go to court to fears that the public were "not on our side ' It was not public opinion, however, but editorial opinion that was against them "*The Times* has repudiated Spens Let no dog bark" A motion calling on the council to test in the courts the validity of Spens as a legal contract for general practitioners was defeated

PARALLEL DECISIONS

Dr A BEAUCHAMP, chairman of the annual conference of representatives of local medical committees, told the meeting of decisions taken at the conference on June 6 In view of the statements made publicly by the chairman of the Royal Commission and assurances given to Dr Wand by the Minister of Health, the conference recommended that evidence should now be given A decision on withdrawal should, it was agreed, be deferred, and another recommendation was that "the negotiating machinery be revised with a view to establishing effective coordination between the several branches of the profession and the prevention of unilateral action by any one branch" A motion was also passed instructing the General Medical Services Committee, in consultation with the council of the B M A, to prepare plans for an alternative national medical service

In England Now

A Running Commentary by Peripatetic Correspondents

ALL normal boys want to be engine-drivers when they have nannies. Later their ideas develop and the nannies have to go. My nanny went too, but something went wrong, something in me failed to develop, and I have only lately discovered what it was. All through my school years, through M.B., B.S. to M.D., through houseman, S.H.O., registrar, S.H.M.O. and consultant pathologist, through my military service, I wondered what was wrong with me. During all my years of dutiful seaside holidays with the family I wondered why I was unhappy. Now I know—I still wanted to be an engine-driver.

And so it is that every holiday now finds me a "passed fireman" on the books of an old-time, half-size, obsolete railway line in Wales, alongside dozens of others suffering from the same complaint. I light the engine-fire and watch "her" get up steam, I clean and polish her, and then move her along to pull her train out. I talk railway jargon. Sometimes I forget and the passengers become patients. My companions are a cross-section—professional railwaymen, tally clerks, fitters, solicitors, policemen, accountants, lorry-drivers, company directors, and of course clergymen. Occasionally I see a colleague and I tease him. Yes, he remembers the face. 1938? St Mary's? The engineman's cap and overalls, the covering of coal and grime, overwhelm his cerebral processes and they grind to a halt. How can a contemporary be working thus? Unless, yes, that must be it. It must be the work of the General Medical Council. After all it might happen to anyone. Volunteer, did you say? This is only a summer holiday hobby? Recognition dawns, freely, honourably, and obviously. Of course he remembers, and what a wonderful hobby. Reminiscences are interrupted by a shriek of the whistle. "Right away" it is, and the train moves off.

May I never grow up.

* * *

Occupational medicine in the North is a bit of a change. I now syringe ears to strains of *Music While You Work* and am no longer surprised by a "How do you do" in response to a proffered "Good morning." The uniformed gatemen have ceased to look grim and hostile, and their welcoming smile and wave compensate for the evil odours that assault me as I enter the factory. I drive past glistening rows of fitters' cars in my twenty-three-year-old vehicle, but realise that the display will save me a visit to the show-room when my ship comes home.

There are many surgery attendances on Mondays, when industrial hazards are eclipsed by football and Judo as sources of trauma. The chairman seems to burn as well as a shop-steward at the business-end of the cautery, and I find that the pain of a "strained back at work" may emanate from a renal calculus. I live in suspense lest patient and first-aider should meet before the former reaches the medical centre; the practical effect of some answers at a recent viva would best be untried. There is an abundance of monosyllabic Christian names and a pleasing democracy extends even to the golf-club. I lately arrived at the first tee to admire the drive of someone whom I had that very day restricted to sedentary work.—But perhaps the amended certificate next morning was an aid to productivity. No discussion was necessary and a "fit" note thus achieved might be considered a "knock-out" as against the "win on points" which is so much more exhausting to the doctor.

At first the impact of industry depressed me, but after a few months the sullen faces that greeted a first anonymous tour of inspection were replaced by those of friendly patients, whose foibles are appreciated and who have themselves learnt that a description of the terrible job they are doing does not fall on green ears and may elicit a rapid and conclusive visit to the site. I find that the girls on seemingly monotonous and soul-destroying packing operations wouldn't change jobs if they had the chance—"what, use my brains for the company?" They are far happier gossiping about boy friends and giving each other verbatim reports of the latest films. The greatest disturbance in their factory life is a change of working group. The art of evading leading questions is tested to the utmost, for in general practice I did not lunch daily with my patients and their associates. It is, however, possible to keep a check on the managerial coronaries by well-directed glances when the chipped potatoes are in range of unsuitable recipients.

Also I have a very nice pair of industrial shoes for which I paid 36s.

* * *

William, aged 12, represents the small line of pure-bred countryfolk still discernible among the welter of immigrant technicians in our Surrey town. Though by no means stupid, he is artless and all-trusting. His middle-ear infection had flared up a few weeks before his visit, and was now smouldering like a tired volcano, with an indolent lava-stream of pus lying on the meatal floor and the main furnace-flames visible, slowly pulsating, through the central perforation. The temptation to leave the healing to Nature was great, but the temptation to use an antibiotic was greater, and after a rapid twist of the mental roulette I settled for a well known topical preparation in propylene glycol. "Use these drops in your ear three or four times a day," I said, "right?—And come again in a week."

He came. "How is the ear?" I asked. "Much better, thank you, doctor" he replied. "No discharge any more?" I asked. "No, thank you, doctor," he replied. "Well, let's have a look," I said, "Let's see now, which one was it?" "This one," he answered, pointing to the right. "Are you quite sure?" I queried. My notes said definitely it was the left. "Yes, doctor," he replied, "you said put them drops down the right ear and that's wot I done like you said, doctor."

I clapped a mental hand to my psychological brow and groaned inwardly. Then picked up the auriscope and looked. Sure enough, the volcano was extinct, no lava, no fires. The drum and meatus were clean and dry.

My thesis on the value of contralateral topical antibiotics in otitis media will soon be in the Editor's hands.

* * *

My new secretary smokes cigarettes but reads all your articles and letters about cancer and types out all my P.M. reports on cases of secondaries in the brain. The result is she is developing an anxiety state, and smokes more cigarettes than before.

* * *

My wife's description of her first air trip. It's wonderful—everything is done for you. It's just like having an operation.

Little Nurse Delaney has been taken away
And oh! the difference to me!
She was the one who shook me pillows
Into a billow of cool white clouds
And when dawn came jade green
And the thrush began its lyric stave
On the chestnut tree outside my ward
She brought in the toast
Thin, hot,
No frame of tough crust.
Her fingers rested
Imponderably
On the fevered pulse
(The new wench grips your wrist
Like an officer of the law.)
And she was the nurse
(My own Delaney)
Who took my teeth away
To wash under the tap
And brought them back
Cleansed, fresh washed,
Pleasant to taste.
Oh where is my Delaney
Who pulled unruly ridge
From under draw sheet mackintosh?
And served me bed pan
Warm as her own heart?

Letters to the Editor

CONTROLLED TRIALS NEEDED

SIR,—I was delighted to read your annotation of June 15 about the need for controlled trials of therapy in hypertension, for this is a subject that has been causing us much worry in our hypertensive clinic

Up to the present time the medical control of hypertension has involved the use of drugs such as hexamethonium or pentolinium, together with reserpine, and the patient's life has been made difficult by the need for rigid control and the liability to side effects Under these circumstances we have felt it unjustified to treat symptomless or mild hypertension and treatment has been reserved for those patients who had severe hypertension marked symptoms and a bad prognosis

The recent introduction of mecamylamine may have altered this situation, for this drug appears to produce satisfactory control of blood-pressure with less risk of sudden hypotension and with little disturbance other than constipation It is preferred by almost all our patients who have been transferred on to it from hexamethonium

The group of hypertensive patients who cause us most concern are the young men, between 25 and 35 who are found, often by chance to have a raised blood-pressure due to essential hypertension The ultimate prognosis in these patients is poor, and many may develop serious symptoms or signs in the course of a few years

A controlled trial of medical treatment in this special group of patients is urgently needed As you say in your annotation such a trial requires a cooperative effort It presents far greater difficulties than the trial of streptomycin in tuberculosis for not only must it be continued for years, but the subjects will feel fit and will be at work and yet their full coöperation is essential So is that of their general practitioners Another difficulty is that such a trial cannot be a blind one for it will be obvious to both the patient and the doctor that an active constipating drug is being used

I hope that as a result of your suggestion, the Medical Research Council or some other body will investigate the possibility of organising such a large scale controlled trial We must find out whether the outlook for such patients can be improved by drugs but the trial will also have to answer the question as to whether the end results justify the anxiety that must necessarily be aroused by such early treatment

London W C 1

M L ROSENHEIM

CONSULTANT AND SPECIALIST

SIR,—On behalf of S.H.M.O.s I wish to thank you for so lucidly putting the case for an increase in the number of fully trained specialists in the National Health Service With the exception of the last paragraph of your leader of June 1 S.H.M.O.s are in sympathy with your views But the final paragraph is far from reality for instance the fear that the Ministry would swell ranks to get cut price consultants is not baseless this may not be the intention but in practice this is precisely what is being done throughout the country Where there is a limit on the expenditure of regional boards, S.H.M.O. posts are created in place of consultant posts On one occasion an administrative medical officer said "we cannot manage a consultant but we could run to a S.H.M.O."

The profession did suggest a definite ratio in the report on hospital medical staffing This ratio was deleted altogether in the final report when returned from the Ministry and the proposed new grade had absolutely no safeguard against its unlimited expansion in *all specialties*

Your statement that our representatives have had no difficulty in securing strict observance of the agreement for limitation of S.H.M.O. posts" is not true There has been gross abuse of the grade as follows

(1) There has been a big expansion of the grade as compared with the consultant grade especially in certain specialties such as chest diseases and psychiatry

(2) S.H.M.O. posts have been created where definite consultant work is to be done on the grounds of supervision" by a consultant who is miles away and who in certain cases never visits the hospital or clinic

(3) Figures of S.H.M.O.s as given in official lists are misleading as the general practitioner S.H.M.O.s who retire or leave the service are seldom replaced by S.H.M.O.s the positions are offered to G.P.s as clinical-assistant posts

Any new grade whether it is called assistant consultant, trained specialist or as at present, S.H.M.O. must be controlled by a strict ratio approved by the profession and accepted as a strict rule by the Ministry

POSTOPERATIVE COLLAPSE DUE TO ADRENAL INSUFFICIENCY

SIR,—I was very interested in the paper by Mr Slaney and Mr Brooke (June 8) because their experience agrees closely with my own There are however, other relatively common causes of postoperative adrenal failure which are not generally recognised

The causes of adrenal failure may conveniently be classified as follows

Primary adrenal failure

Removal	adrenalectomy
Destruction	Addison's disease, traumatic adrenal apoplexy
Exhaustion	toxæmia and starvation
Dysfunction	virilising hyperplasia

Secondary adrenal (primary pituitary) failure

Removal	hypophysectomy
Destruction	Simmonds's (Sheehan's) disease pituitary tumours
Inhibition	therapy with cortisone and its analogues and with corticotrophin

I would like to comment on two of these

First Addison's disease may easily be overlooked, especially in an emergency in a patient with some other condition which requires surgery Operation is followed by peripheral circulatory failure which may well prove fatal In early or mild cases the first clinical sign of adrenal insufficiency may be severe prolonged hypotension after the stress of an operation In such circumstances if no cause can be found for the collapse and if there is no response to blood transfusion, adrenal insufficiency should be suspected and treatment with noradrenaline and hydrocortisone should be given at once The noradrenaline can be withdrawn when the hydrocortisone starts to take effect On several occasions this has proved life saving

Secondly, starvation which may cause 'adrenal exhaustion,' is not uncommon in patients who have to be "dripped and sucked" for long periods after an operation I have had two such cases in the past year—one following gastrectomy and one after transplantation of the ureters—in both of whom the systolic blood-pressure fell to about 80 mm Hg after 2 to 3 weeks Adrenal insufficiency was suspected in both hydrocortisone was given, and the blood-pressure was restored to normal within 24 hours

Death from adrenal failure must be regarded as a tragedy since it is largely avoidable Experience has led me to formulate the following rules

(1) The conditions which may cause adrenal failure must be borne in mind

(2) If time allows adrenal function should be assessed before operation in those in whom it may be deficient

(3) Supportive therapy should be given when necessary If in doubt it is better to give support than to withhold it

(4) The clinical picture of adrenal insufficiency must be recognised early and the condition should be suspected in any case of unexplained hypotension following an operation

(5) Treatment must be given as soon as the condition is suspected, otherwise it may be too late The therapeutic response to hydrocortisone is often the only way of confirming the diagnosis

A fuller account of this important subject was presented to the surgical section of the Royal Academy of Medicine in Ireland in February and is now in the press

SERUM-LIPIDS IN ISRAELI COMMUNITIES

SIR,—In view of the topical discussion on the ætiology of atherosclerotic coronary-artery disease and its relation to hereditary and nutritional factors, we would like to refer to our research in Israel [1]

Among the Jews in Israel, there is a homogeneous group of Ashkenasian Jews, whose ancestors lived in Europe for hundreds of years and, for the past 80 years, in the United States of America and South Africa On the other hand, the forefathers of the Sephardic community lived in the countries of the Middle East or among the Arabs The same mortality and morbidity from arteriosclerotic and from coronary-artery diseases prevails among Ashkenasian Jews as generally in England and the United States, Sephardic Jews, on the other hand, are much less prone to these disorders Among Sephardic Jews there exists one community, the Yemenites, of whom there are now in Israel 118,800 people Coronary-artery disease is practically unknown among Yemenites, and hardly any clinician can recall Yemenite patients with myocardial infarction in his ward

The Yemenites are Jews who have lived for thousands of years in the Yemen, in the peninsula of Arabia They lived in a secluded society having no relations with any other Jews in the world, they were also very little in touch with the Arabs surrounding them As a result they preserved the traditions and the way of living of biblical Jewry, and Hebrew remained the language of daily use during all the years of the Diaspora

We examined the serum-cholesterol, serum phospholipids, and cholesterol/phospholipid ratio in four groups of healthy males—recently arrived Yemenite immigrants, Israeli Arabs, Yemenites who had lived for 25 years in Israel, and Ashkenasian Jews Each group consisted of fifty men aged 35–50 Later we added another group of twenty-five men who had had myocardial infarction (clinical and electrocardiographic diagnosis) As the average age of these men was higher than that of the healthy groups, another series of matched controls (same age and community membership) had to be taken into account Most of the men in these two groups were Ashkenasians

The recently arrived Yemenite immigrants had a very low serum-cholesterol (see accompanying table) It was even lower than the average serum-cholesterol in the Bantu [2] On the other hand, the levels in Ashkenasian Jews were equivalent to those seen in Western Europe and the United States Between these lay the other two groups The serum-cholesterol and serum-phospholipids of patients with myocardial infarction were higher than those of the healthy Ashkenasians and resembled those cited in the literature The values of the matched controls were the same as those of the healthy Ashkenasians Thus it was not the age difference which caused the rise in the plasma lipids

The various differences in the serum-cholesterol from group to group were definitely statistically significant

The difference between the serum cholesterol in the recently arrived Yemenite immigrants and that in Yemenite residents was also definitely statistically significant, but there was almost no difference in the serum phospholipid levels between the two Yemenite groups As a result the cholesterol/phospholipid ratio in the Yemenite residents was much higher than in the recently arrived Yemenites and amounts even to a little more than this factor in the Ashkenasians Gertler et al.[3] thought that the cholesterol/phospholipid ratio was a more important measure of atherogenic activity than the level of either single lipid

The change in a Yemenite group in one generation is expressed in a rise in serum cholesterol without a corresponding rise in the serum phospholipids In general the way of living in Israel is the characteristic Western way, and we want to suggest the possibility that this change may give us a clue to the kind of acclimatisation that takes place in the lipid metabolism of Yemenite immigrants The differences between the two groups of Yemenites also contribute a point to the discussion whether the variations of lipid levels are the result of hereditary or of nutritional and other environmental factors The experience with Yemenites in Israel shows that there is no significant hereditary factor present

Lately we surveyed the nutrition of a group of recently arrived Yemenite immigrants

These Yemenites are peasants who live in a *moshaw ovdim* (a village with communal distribution of the soil) near Jerusalem They live by agriculture and most of them also partly on paid day labour The nutritional survey was done by Yemenite nurses who could make easy social contacts with the tested individuals The nurses lived in the village during the period of the survey and weighed the food of all male members of the families for a whole week Thus, twenty five men, 35–50 years old, were examined individually for a week The results showed that these Yemenites ate food yielding 2200–3000 calories a day The main part of their nourishment was bread (on the average 600–900 g a day), which means that they received the greater part of their calories and proteins from bread They ate on the average 30–50 g fat a day—i e, about 11–18% of their daily calories were derived from fat They ate many raw vegetables and very little cooked food They used much spice Cheese, margarine, and butter were entirely unknown to them They dipped their bread in olive oil or similar vegetable oils, and used them for cooking

The customary food of the Ashkenasians in Israel is similar, in its form and composition, to the usual food in England and the United States

SERUM-LIPID LEVELS IN MEN OF VARIOUS COMMUNITIES IN ISRAEL

Group	Average age (yr)	Average serum cholesterol (mg per 100 ml)	Range	Average serum phospholipids (mg per 100 ml)	Range	Average cholesterol/phospholipid ratio	Range
Ashkenasians	46 1	231	148–346	305	235–415	0 76	0 52–1 07
Yemenite residents	46 3	194	128–279	251	185–358	0 77	0 60–0 95
Arabs	47 0	177	105–304	270	213–317	0 66	0 45–0 90
Recent Yemenite immigrants	44 9	149	98–208	251	182–416	0 61	0 35–0 93
Myocardial infarction	53 0	299	201–413	328	246–425	0 92	0 70–1 35
Matched controls	53 0	228	154–354	301	243–380	0 75	0 54–1 02

It seems to us that all these results may add a little more to our knowledge of the relations between nutrition, lipid metabolism, and coronary-artery disease

X RAYS AND LEUKÆMIA

Sir,—Professor Sonnenblick's letter of June 8 asking for further information regarding the work of Dr Stewart and her colleagues in relation to possible risks attached to radiodiagnosis in pregnancy is a valuable contribution to this problem The greatest possible publicity should be given to all evidence which points in a different direction, lest patients be wrongfully deprived of life-saving information He is apparently unaware that a much more exhaustive survey is in progress here, at the instigation of the British group, and it is to be hoped that other countries may follow our lead

It is, however, deplorable that he should take exception to your publications on this subject as premature His pontifical and avuncular judgments read oddly in an age when freedom of expression of scientific opinion has been accepted, they would have been familiar to Galileo

I have no doubt that you, Sir, will continue to publish communications from qualified persons, and from departments of repute, regardless of the corns that may be exposed to trauma, on either side of the Atlantic

The quickest way to dispose of data wrongly interpreted is to publish them as soon as possible The sooner doctors learn of possible risks to their patients the better In an age bedevilled by political issues and vested interests in all aspects of radiation, nothing but harm can issue from attempts to impose a censorship on scientific and medical publications No important scientific fact has ever been established without honest contradiction by well-qualified experts

CIRCUMCISION WITH BONE-CUTTERS

Sir,—I was interested to read Dr Skeggs's contribution (June 8) towards greater safety in the technique of circumcision using bone forceps I agree that this method is employed only too seldom, and this is all the more unfortunate in view of its many advantages Few operations offer such economy of time or materials, with complete absence of bleeding, and by comparison with the conventional alternative it assumes a distinctly æsthetic nature (leaving strictly aside all controversy as to indications for operation)

There is no doubt that its lack of popularity in this country is mainly due to the very natural fear of injury to the glans Another important factor is failure to obtain separation of the two mucosal surfaces without disturbing the sealed mucocutaneous edge The resulting hæmorrhage and crestfallen call for sutures forms an embarrassing anticlimax to an impressive bloodless amputation

In order to prevent this latter complication I should like to describe another point of technique which I have found of help This is to insert a slip of corrugated rubber underneath the foreskin so that it lies alongside the glans The bone forceps are then applied On their removal, the corrugated rubber has sufficient resilience to spring apart and reveal the correct plane Further separation is then easily effected with a dissecting forceps with no risk of disturbing the mucocutaneous seal

A further word to nervous beginners one should not confuse the sensation as the bone forceps cuts through the rubber and think that the worst has happened! This has often given my younger colleagues an unnecessarily anxious three minutes

Glasgow Royal Infirmary **F T Crossling**

TOWARDS SAFER CLOTHING

Sir,—The marketing of flame-proofed materials and garments is at the moment in the stage of "teething troubles"—hence Dr Woodliff's difficulty (June 1) in getting pyjamas About a year ago several manufacturers became interested in one process of proofing, but the price was high and the makers ran into some technical difficulties when they started applying it on a large scale, with the result that some samples supplied to the shops were stiff and did not stand up to hard wear for children's clothes This was unfortunate and has given a set-back to the supply and demand

Meanwhile, at least two other processes have been undergoing trials but naturally the manufacturers prefer to go slow and not risk another false start It is hoped (but not certain) that one or both of these may be ready for the market by next autumn—and perhaps also an improved version of the original process

Other possibilities are also on the way For example, one firm has produced a very attractive "raised" nylon which may well become a serious competitor to proofed flannelette, but this has not yet completed its trials I gather

The best plan for the time being, to avoid unproofed flannelette, is to get pyjamas of a light weight woollen material, or of ordinary nylon or 'Terylene' (Mixed wool and cotton are almost as flammable as cotton alone)

Farnham Royal, Bucks **Leonard Colebrook**

AUTO-ANTIBODIES IN ADDISON'S DISEASE

Sir,—The claim made by Dr Anderson and his colleagues (June 1) that they have demonstrated an auto-antibody to adrenal tissue in patients suffering from Addison's disease is of considerable interest Although this was a preliminary communication, we feel that it is open to criticism

Firstly, no proof is produced that the complement-fixation reaction they have encountered is truly immunological—namely, that it is a property of the globulin fraction of the serum and that it can be inhibited by absorption of the serum with a specific antigen Secondly, their suggestion that two different antibodies are involved in the reactions between the serum and extracts of thyroid and adrenal is not supported by cross-absorption or gel diffusion tests, or by accurate titration of the serum against the two extracts Thirdly, the presence of an organ specific antigen, such as thyroglobulin, has not been demonstrated Failure to acquire immunological tolerance has been suggested as the explanation for Hashimoto's disease It is difficult to conceive of any derivative of the adrenal which is normally shut off from contact with sites of antibody production in a manner similar to thyroglobulin and which could therefore become an auto antigen Fourthly, there is no evidence, as yet, that the antibody detectable in Hashimoto's disease is actually responsible for the pathological changes, though it would appear that this is so in the rabbit immunised with its own thyroid gland [1] Fifthly, if the reaction is an immunological one, Dr Anderson and his colleagues have demonstrated an iso antibody rather than an auto-antibody This is true of the work of Roitt et al [2] in Hashimoto's disease, though it has subsequently been shown that an auto antibody occurs [3]

It is to be hoped that these questions will be answered soon and unequivocally Many unconfirmed claims of the presence of auto antibodies have been published in the past decade Some of these have been critically reviewed in your columns [4] and similar criticisms are applicable to other work With the exceptions of paroxysmal hæmoglobinuria and Hashimoto's disease, there has been no unequivocal demonstration of an auto antibody in human disease We feel that it is important that strict criteria, such as those laid down by Witebsky at the meeting of the British Society for Immunology last month, should be *fulfilled* before the presence of auto antibodies is claimed or accepted in any disease

SEASONAL INCIDENCE OF MEGALOBLASTIC ANÆMIA OF PREGNANCY AND THE PUERPERIUM

SIR,—I feel that Dr Thompson's reference (June 8) to a paper by Vinke and Van der Sar[1] should not pass without comment The statement made by these Dutch workers is "As the minimal quantity of folic acid required by man is 200 µg a day (Williams et al 1950[2]), the stock in the liver is sufficient for 15 or 30 days when the diet is completely lacking in folic acid" This is used both by Dr Thompson and by the Dutch workers as an explanation of why megaloblastic anæmia of pregnancy in temperate zones is due to deficiency of folic acid rather than vitamin B_{12}, it is generally agreed that the stores of vitamin B_{12} will last for months or even for years

The fact is, however, that this theory has not previously been accepted because the daily requirements of the human for folic acid are quite unknown They *may* be 200 µg per day, but even Williams et al[2] do not claim this Indeed on p 325 of this book they state that "The quantitative requirement (for folic acid) cannot be closely estimated from evidence now available" The figure of 200 µg per day is put forward by them on p 326 in a table as a recommended allowance in view of the lack of knowledge, and reference is made to a paper by Williams[3] which in fact says that it is not even known that folic acid is required for the human (This was in 1942)

It is easy to observe a human developing vitamin-B_{12} deficiency, since this will occur after total gastrectomy because of lack of intrinsic factor, but to produce folic acid deficiency alone is not practicable

However, some idea of the order of magnitude of the daily requirement of folic acid might be obtained by finding the minimum effective daily oral dose in patients with nutritional megaloblastic anæmia who had normal folic-acid absorption, a normal serum-vitamin B_{12} level, and normal absorption of labelled vitamin B_{12} Another less physiological method of approach would be to find the minimum effective daily injected dose in patients with idiopathic steatorrhœa and megaloblastic anæmia whose absorption of labelled vitamin B_{12} was normal and whose absorption of folic acid was impaired In both instances the possibility of complicating ascorbic-acid deficiency would require consideration, and in any case some of the administered dose might be deviated to functions other than restoration of normal erythropoiesis

It is likely that some cases of megaloblastic anæmia in pregnancy in temperate regions are due to folic acid *deficiency* and in some instances the output of folic acid after a test dose has been low[4] However, many patients with extremely poor diets do not develop megaloblastic anæmia in pregnancy, and some who do develop it are in good circumstances, eat a normal diet, and have no complicating factors such as vomiting, diarrhœa, or multiple pregnancy To complicate the matter even more, Okuda and his co workers[5] in Baltimore have claimed that very low serum vitamin B_{1} levels may be obtained even in normal pregnant women at the time of delivery, and consider that the fœtus deprives the mother of the substance

In summary, the theory of Vinke and Van der Sar is attractive, but we do not really know whether the body stores of folic acid will last for 30 days or for 600 As Dr Thompson says, dietary deficiency is probably an important contributory cause in megaloblastic anæmia of pregnancy even in temperate climates, but other unknown factors appear to play a part

DIVISION OF INTERCOSTAL ARTERIES

SIR,—In your report of the Anglo French surgical conference (June 8) the question of dividing intercostal arteries and the safety of doing so was raised by Jean *Cauchoix and Jean-Paul Binet* with the words "*there* is still no final answer in man"

Presuming the danger to be interference with the circulation of the cord, I should like to point out that the circulation of the cord was worked out by Kadyi in 1889 and his work confined by Suh and Alexander in 1939 The latter point out that Tanon emphasised the importance of the lumbar radicular vessels in the blood supply of the whole cord and that the middle thoracic section of the spinal cord has the *poorest local segmental* circulation

Our experience supports this in 106 cases of anterior fusion, Prof F E Stock and I have divided up to as many as eight intercostals in a single patient without any complications I think the most dangerous area is the lumbar and it is in the thoracolumbar region that the danger lies *I hope this will fortify those who might* be deterred from using this excellent approach to the thoracic spine by the words "there is still no final answer in man"

MECHANISMS OF PERIODIC PARALYSIS

SIR,—It was with particular interest that I read your leading article of April 20 and the article by Professor Conn and his colleagues in the same issue

I agree entirely that the underlying mechanism of periodic paralysis is not identical in all cases At least one other condition can produce symptoms similar to *those of familial periodic* paralysis In April, 1956, I described[1] a disease which, like periodic paralysis, is characterised by attacks of paralysis, especially during rest after exertion The disease is hereditary and the inheritance is due to a single, autosomal, dominant gene with complete or almost complete penetrance Clinically the disease differs from periodic paralysis in the following respects it begins earlier in life (in 90% before the age of 10 years), the attacks are more frequent, shorter, and less severe (75% of the patients have at least one attack a week, and the attack lasts at most 1 hour, during which the patient is usually not completely helpless), the attacks are more liable to occur when *the patient* is hungry, and the intake of food, especially of bread, has a good prophylactic and therapeutic effect During an attack the serum-potassium is increased without any accompanying decrease in the urinary excretion of potassium, and the electrocardiogram shows high pointed T waves Like rest after exertion, 1–2 5 g of potassium by mouth will precipitate an *attack* The administration of glucose has a good prophylactic effect

Of the published reports of familial periodic paralysis, some, such as that of Tyler et al,[2] appear to fit in well with the picture of adynamia episodica hereditaria In other words, the description of the mode of inheritance, the clinical picture, the absence of decreasing serum-potassium during an attack, and the lack of response to potassium therapy suggest that the patients really had adynamia episodica hereditaria.

---

[1] Gamstorp I *Acta pædiat Stockh suppl* 108 1956
[2] Tyler, F H Stephens F E, Gunn, F D, Perkoff, G T *J clin Invest* 1951, 30, 192

Since Tyler et al found vacuoles in the muscle-fibres, this finding cannot be pathognomonic of periodic paralysis. The mechanisms of the two diseases must be different, which does not, of course, exclude the possibility of vacuoles occurring in the muscle-fibres in both conditions. Microscopic examination of muscle-biopsy specimens from 3 of my patients, however, failed to reveal any such vacuoles.

Barnsjukhuset, Lund, Sweden. INGRID GAMSTORP.

CHILDREN IN HOSPITAL

SIR,—What a pleasure it is to read a paper like that of Dr Vaughan in your issue of June 1. The point of his investigation—the presence or absence of explanation to children, before admission, of what was going to happen to them in hospital—is an important one. As he points out, most of these children were confused and frightened on admission, and twenty-six weeks after discharge 11 of the children to whom no explanation had been given, as against 3 of those to whom matters had been explained, were still disturbed.

This inquiry raises a point very familiar to child psychiatrists—of the loss of confidence in their parents felt by children given lying statements by their parents about the reasons for their visit to a hospital of which inpatient admission is the (to the child) unexpected outcome. As Dr Vaughan reports, some parents are unable to explain what is to happen to their children and some are definitely frightened to do so. At present no provision is made for the preparation of children about to come into hospital in our outpatient and inpatient routine handling.

During two years spent in the wards of the Royal Hospital for Sick Children, Glasgow, under Prof Leonard Findlay on an M R C inquiry which involved direct contact with the children's families, I was much struck with the help that could be given, both to the progress of the child in hospital and to wise aftercare by his family, by simple explanations to both sides concerning the procedures the child was experiencing in hospital.

As Dr Vaughan points out three things are necessary: (1) explanation to parents of the importance to their future relations with their children of a truthful account of the reasons for the child's visit to hospital, (2) explanation to the child himself of what is going to happen to him in hospital (and in every case this should include explanation of the meaning of, to the small child, so mysterious a procedure as the use of the injecting needle), and (3) opportunity for the child to express his fears and receive comfort and reassurance.

Is not this a sound opportunity for coöperation between the psychiatric and the pædiatric branches of our children's services? And would something like the following not possibly meet the case?

(1) The psychiatric social worker, should there be one in the hospital, or if not a member of the nursing staff with special training to meet this need, should have a talk in the outpatient department with each mother whose child has been put down for admission to hospital. Such an interview should contain an explanation of what is to happen to the child while in hospital and persuasion of the mother to prepare her child for it. Fear is catching; children catch it from their mothers. Such a procedure would give an opportunity to the mother to ventilate her own fears about hospital admission for her child and to be reassured.

(2) In every children's department, and particularly in relation to surgical wards, it should be the duty of one of the resident medical staff to see all children for a brief period immediately after admission to explain to them carefully just what is about to happen, and to assure them of a future friendly visit and opportunity for a talk over anything that has puzzled or frightened them shortly after the completion of an operation.

(3) All outpatient children's physicians should be asked, on the child's reporting visit after discharge from hospital, to inquire specifically about symptoms of disturbance, and if these are present to refer the child at once to the psychiatric clinic.

(4) Simple leaflets should be prepared for use in the outpatient department and by general practitioners, setting out clearly the importance of explaining to children going into hospital what is awaiting them, and telling parents whom to ask if they are puzzled as to how to do this or if they later find their child upset by his experiences in hospital. The parent bringing the child to outpatients could be encouraged to take this leaflet home to discuss with the other parent and older members of the family, so that a period in hospital for a child could become more of a corporate event in which all the family is interested, instead of being, as so often at present, a mysterious experience in which the child feels afloat on a very small raft out of sight of familiar land or faces.

As a step towards the achievement of these objectives, would it not be possible for the child psychiatrist to the hospital to give short talks to nursing and resident staff, explaining the grounds for these additional, and which may seem to an over-worked staff tiresome, additions to routine and the good harvest that can be reaped by them in understanding home management of their small patients after discharge and an increase in mental health of the children?

London, W 11 MARGARET LOWENFELD

EPIDEMIOLOGY OF POLIOMYELITIS

SIR,—In your leader of April 20 you say "Recent studies have made clear the reasons for the striking differences in the incidence of paralytic poliomyelitis between countries with high and with low standards of living."

The evidence brought forward fully explains the rising age incidence in countries with a high standard of living but, as Dr Pease and I[1] recently pointed out, it does not explain the recent increase in paralytic disease in under-developed countries, nor the variation in the severity of attack in countries with a high standard of living (cf Denmark in 1952).

Hammon et al[2] have suggested that paralytic poliomyelitis in the Philippines may be due to the importation of "paralytic strains" from the United States, and a similar explanation *could* account for the epidemics in Malta and Madagascar during the late war and in many other countries, such as Israel and Kenya,[3] since then.

In other virus diseases, such as smallpox, strains exist of the same immunogenic type, but of varying virulence and giving rise to a varying severity of illness.[4] In smallpox the difference in virulence is so marked that two distinct forms are recognised and known as variola major and variola minor, or alastrim.

Clinical cases of poliomyelitis are most frequently associated with type 1 viruses, but evidence is accumulating that the severity of an epidemic depends more upon the virulence and neurotropism of the strain of the virus than upon its type.

Tanganyika is a country with a low standard of living and very poor communications, and yet in 1954 there was a severe localised epidemic of paralytic poliomyelitis among susceptible infants, with 99 cases among a total population of approximately 100,000, and in 1956 there was an even *more* severe outbreak at Kilonko with an incidence of 275 cases in a similar population.

The fact that paralytic poliomyelitis, or "polio major," has taken so long to penetrate Africa since its first appearance in the 1880s, is probably due to the high degree of immunity which has been developed there by repeated epidemics of "polio minor" and to the difficulties of communication. The existence of previous epidemics of the non-paralytic disease is shown by the immune state of the majority over the age of 5 and by the sporadic cases of paralysis that have occurred in the past. Their existence is further supported by the type of research carried out by Melnick et al.[5] to which you refer.

CÆSAREAN SECTION

SIR,—Few of your readers interested in modern cæsarean section would endorse all the views expressed in your leading article of April 6. Many would be in fullest agreement with Prof. Dugald Baird and Mr. Terence Robinson (April 27) and Mr. Higgins (April 20). Merely to repeat the view that all other methods of delivery will become obsolete is to perpetuate an absurdity.

Dr. Salzmann's letter (May 25) calls for comment. In a symposium on general-practitioner midwifery services last year,[6] it was pointed out, in discussing the place of cæsarean section, that a survey of 30 large maternity hospitals, mostly teaching, for the five years 1951–55 showed the section-rates to vary from as high as 14% to as low as 1.5%. These units included all the well-known British teaching hospitals as well as prominent units in the U.S.A., Australia, New Zealand, and Eire. It may well be true, as Dr. Salzmann states, that some hospitals in this country show what may be deemed an unnecessarily high section-rate, but the average yearly rate for the group of hospitals analysed was 5.1%, and if the results of the group studied by Marshall and Cox[7] are re-examined for the period 1951–55 the average yearly rate is shown to be 6.1%, which is almost exactly the figure quoted by those authors for 1943–1947—i.e., 6.2%.

The criticism by the prominent member of the Royal College of Midwives, to which Dr. Salzmann refers, seems therefore a little ungracious without a fuller knowledge of the conditions obtaining in the particular hospitals to which she alludes.

ANÆSTHESIA FOR CÆSAREAN SECTION

SIR,—The letter by Dr. Margaret Watkinson (June 15) has stimulated us to make a plea for the abandonment of the long established ritual of "slash-and grab" cæsarean section. For the obstetrician who stands beside his patient about to be delivered by cæsarean section, prepared with scalpel poised to extract the fœtus at a word from the anæsthetist, will allow his forceps cases to be anæsthetised whilst preparing the vulva, catheterising, and draping the patient before he is ready to commence vaginal delivery. Forceps extraction is then performed slowly and deliberately, without haste or rush.

It is our practice to anæsthetise patients for cæsarean section before subjecting them to the frightening experience of skin preparation and draping. The operation itself is unhurried and the benefit to the mother of the slower and gentler surgery has been achieved without increased risk to the fœtus.

The anæsthetic technique employed is briefly as follows:

Induced by the inhalation of cyclopropane and oxygen, the patient is maintained at the lightest possible plane of surgical anæsthesia with nitrous oxide and oxygen, augmented with a little cyclopropane if necessary. All cases are intubated, a cuffed Magill orotracheal tube being passed under suxamethonium (succinylcholine) induced paralysis. Respiration is controlled, relaxation being produced by intermittent administration of suxamethonium, and light plane anæsthesia is maintained with nitrous oxide and oxygen.

It is not our intention here to advocate any one method of anæsthesia for these cases, or to compare general with local, spinal, or extradural anæsthetic techniques. Neither is unnecessary slowness condoned; in cases of fœtal distress surgery is performed with expedition, as in forceps delivery for this condition.

We make no claim to originality in contending that no greater speed is required in delivery of the fœtus per abdomen than per vaginam, and that, with an anæsthetic technique embodying good oxygenation with a light plane general anæsthetic, "slash and grab" cæsarean section is a ritual to be abandoned.

MECHANICAL FACTORS IN ATHEROSCLEROSIS

SIR,—I was very interested to read the article by Professor Duguid and Dr. Robertson in your issue of June 15. The importance of these factors was strikingly demonstrated during some work on post-mortem arteriography by Dr. K. D. Keele and myself.[1] One of the subjects had wasting of one of the lower limbs due to tuberculosis of the hip and knee as a child, and on this side the arteries were almost devoid of disease, whilst those on the other showed all the features of atherosclerosis.

Chertsey, Surrey
C. F. ROSS

INFLUENCE OF THE CEREBRAL CORTEX ON SODIUM EXCRETION

SIR,—A conditioned diuretic reflex in the dog was first described by Bykow and Alexejew Berkmann,[2] who administered water repeatedly per rectum in dogs. After a certain number of trials, taking the dog into the experimental room and putting it on the stand was enough to elicit an increase in diuresis.

In our own experiments, the conditioned diuretic reflex was obtained by giving water by mouth. Loading with water resulted in the well-known phenomenon of unconditioned water diuresis. After a suitable number of experiments the conditioned reflex was established and the diuresis increased without water intake when the dog was on the stand.

In this conditioned diuresis, the urinary excretion of sodium was very high, whereas in the unconditioned diuresis it was very low. To use modern terminology, the unconditioned water diuresis is characterised by a high positive free water clearance, with a negligible osmotic clearance. In the conditioned diuresis, the positive free water clearance is relatively low and the osmotic clearance is high. The "conditioned reflex" nature of the phenomenon is proved by differentiation. Creatinine excretion being virtually unchanged, the cause of the increase in the excretion of sodium is apparently a reduction in tubular reabsorption.

Our observations suggest that the conditioned reflex may differ from the unconditioned reflex, and that the cerebral cortex may also directly influence tubular reabsorption.

A detailed account of our experiments, in coöperation with *Dr. M. Gerbner and Dr. K. Altman*, will be published elsewhere.

Public Health

Training for the New Public Health

THE evolution of a specialty tends to follow a recognisable pattern There is the recognition of a need , the pioneer attempts to meet that need , the hiving-off of the pioneers' successors into a new caste with a special training, qualifications, rituals, and jargon , the inclusion of the specialty's basic content in the undergraduate curriculum , and eventually its expansion at the expense of others, its decline, or its modification Surveys of the status of training in the subject form milestones along the road

A milestone along the road of public health is the World Health Organisation's monograph by Professor Grundy and Professor Mackintosh [1]

To this an international character has been imparted by including summaries of W H O conferences at Nancy (undergraduate, 1952) and Goteborg (postgraduate, 1953), and by submitting the text to leading public-health educators in eight countries In addition there is a factual survey of the position in nineteen countries—perhaps too much compressed, however, for in the fifteen lines given to undergraduate training in London, for instance, it does not bring out the widely varying standards and the relative neglect of the subject in comparison with provincial schools and with many foreign countries Here a comparison with the similar survey by Prausnitz [2] in 1932 would have been interesting

The main theme is the change of emphasis from environmental public health to social medicine—from water-closets to welfare, in fact—which some may reckon a rash change when the subject is in a state of flux Perhaps, therefore, the words "social medicine" should have been included in the monograph's title, particularly as there is a school of thought, notably in Scandinavia and the Netherlands, which holds that public health and social medicine cannot be combined in one professorial chair

It is on such subjects as the three prevailing types of curriculum (traditional, intermediate, and comprehensive social), the problems of nomenclature, and the extent to which social medicine is a specialty that the authors are at their best All concerned should be grateful to them and to the World Health Organisation for their intelligent and important survey of where we are and whither we are likely to go in the ill-defined and almost hedgeless fields of public health, hygiene, and preventive and social medicine

Poliomyelitis

Uncorrected notifications for poliomyelitis in the week ending June 8 (23rd week of the year) were as follows (previous week in parentheses) paralytic 48 (42), non-paralytic 26 (25) , total 74 (67) The following figures compare this year's notifications with those in the preceding nine years

Year	*Total cases up to and including 23rd week*	*Cases in 23rd week*
1948	597	14
1949	383	19
1950	840	79
1951	591	52
1952	603	61
1953	766	73
1954	534	26
1955	419	44
1956	646	55
1957	1084	74

We have received preliminary details of the results of fæces examination of persons in contact with a case of paralytic poliomyelitis in a London borough The patient, a woman, was the first notified case (May 1, 1957) in the borough since February last (there had been 3 non-paralytic cases in children) The rest of the family had been ill with "colds" and "influenza" sixteen days before the mother was taken ill In 2 of her 3 children, as well as a classmate of one of the children, virus was present in the fæces The virus was still present twenty-eight days after the first examination No other cases of poliomyelitis had so far been notified in that district up to June 17 House quarantine was not begun until after the result of the fæces examination of the children was known before this, one of them had been to school

Similar inquiries should help to clarify the value of close quarantine in poliomyelitis, a subject which is discussed in an annotation on p 1290

Influenza

Influenza virus isolated from a traveller lately arrived at the Hague has been sent to the World Influenza Centre in London So far no spread has been reported in Holland Reports reaching the World Health Organisation suggest that the virus responsible for the epidemic in Asia has also arrived in Australia and North America, but no outbreaks have developed [1] The disease remains very mild Viruses sent to the World Influenza Centre from Hong-Kong, Singapore, Kuala Lumpur, Australia, and Japan have all been antigenically alike, belonging to the new so-called Far Eastern variety of influenza A The reported view [2] of Sir Macfarlane Burnet, director of the Walter and Eliza Hall Research Institute in Melbourne, is that the virus will spread throughout the world and that it will arrive in Britain when the cold weather comes

Vaccine against the new type of virus has been prepared in the department of virus research in the Wright-Fleming Institute, St Mary's Hospital, London [3] The first batch will be tested soon

Obituary

MARINUS VAN DEN ENDE

M B Cape Town, Ph D Camb

Prof M. van den Ende, dean of the faculty of medicine in the University of Cape Town, died on June 4 at his home in Cape Town at the age of 45

He was born in South Africa of a family of Dutch settlers, and he was educated at the University of Cape Town, graduating M B in 1933 Four years later he came to this country to take up a John Lucas Walker studentship in the department of pathology of the University of Cambridge, and in 1940 he was awarded the PH D Camb Meanwhile, in 1939, he had joined the scientific staff of the Medical Research Council at the National Institute D G E, one of his colleagues there, writes

van den Ende was a born research-worker, both in the laboratory and in the field, with a highly critical mind and amazing energy, he seemed destined to reach the highest possible position. His researches during the war on cross-infection in hospitals and on typhus were quite outstanding Perhaps his greatest achievement in England was the organisation of the laboratory at Frant for the large scale production of scrub typhus vaccine, exacting and dangerous work which he carried out with tremendous speed and success

Although he was thoroughly at home in England, he never lost the desire to return to his own country, to which he had an intense loyalty, and in 1945 he accepted the chair in bacteriology at the University of Cape Town In this new position he built up a large and active research school in virology and bacteriology and was able to show yet another quality, that of a teacher both of the research-worker and the undergraduate

Apart from his ability as a scientist there were other qualities that will always first come to mind when thinking of van den Ende He was a most lovable person with great charm, he was kind and generous almost to a fault and when, four years ago, he was tragically struck down by his fatal illness he faced the consequences with unbelievable courage, working fervently and relentlessly right to the end Those of us who were with him during his time at Hampstead—which he often referred to as the happiest and most crowded period of his life—realise the great privilege we had in knowing such a man.

Prof van den Ende leaves a widow, two sons, and two daughters

ARTHUR CUBLEY

M R C S

Dr Cubley, formerly deputy medical superintendent of the North-Eastern Fever Hospital of the London County Council, died on June 2, after a long retirement at Ashover, Derbyshire He qualified from University College Hospital in 1900 and his whole career was spent in the fever service of the Metropolitan Asylums Board, and later of the L C C W E S writes

Dr Cubley was for long a well known figure to all the medical staff of a service which was notable for its active inter-hospital social life He had a kindly and unruffled bearing and was always ready to help his juniors from his great store of knowledge of the infectious fevers His upright figure, deliberate speech, and large moustaches perhaps gave an impression more of the countryman than the doctor He had a strong mechanical bent as shown by his invention of the Cubley tracheotomy tube, and he was a skilled woodworker

He leaves a widow

Dr G F BUCHAN

C M S, a county M O H, recalls the one occasion on which he met Dr Buchan

In the early days of the war, when this county had some 40,000 evacuee women and children with all the related multifarious problems, we had many requests from the evacuation authorities to do this and to do that The requests were all perfectly reasonable but nevertheless sometimes trying There was a great sense of relief and contrast when one afternoon a tall distinguished man came into my office and introduced himself as Buchan of Willesden "You have a large number of women and children from Willesden and you must be heavily pressed for health visitors Can I send you some help ?"

Notes and News

SMOKING AND LUNG CANCER

In 1954 a group of tobacco manufacturers in the United Kingdom decided to contribute £250,000 towards research into the cause of lung cancer, and asked the Medical Research Council to apply this fund A year ago the manufacturers set up a standing committee, with Sir Alexander Maxwell as chairman Sir Alfred Egerton, F R S, and Sir Ronald Fisher, F R S, were appointed scientific consultants The committee, which has now issued its first annual report, proposes to set up a new fund to promote research on any problem relating to smoking and health

Mr G F Todd, statistical adviser to the committee, has reviewed various statistical surveys in consultation with Sir Ronald Fisher They criticise studies of the relationship between smoking and lung cancer on the ground that the material was not randomised, the smoking classes being self selected No studies have been made of the causes which determine whether a person will smoke "It would be frankly incredible to assert that these smoking classes are not systematically differential, at least in respect of genotype, if not also in respect of environmental exposures not irrelevant to the subsequent incidence of cancer" If lung cancer were due to direct application of smoke to the bronchial epithelium, it should be commoner in those who inhale than in those who do not, but if it were due to a remote effect, then taking smoke into the mouth might be effective, and lung cancer would be as common in smokers who did not inhale The latter explanation is consistent with the findings of Richard Doll and Bradford Hill, but L Breslow and F Lickint found higher percentages of inhalers among their lung cancer cases than among their controls If both direct application and a remote effect caused lung cancer, the lower mortality rate in pipe smokers would be explained, but at least some increase in inhalers among lung cancer patients would be expected

Non causal explanations of the statistical relationships are considered A genetic factor might increase both the tendency to smoke and the liability to lung cancer The increase would then be explained either by an environmental factor (such as the increase in oxidation products of hydrocarbons in the atmosphere) or by an increase of the numbers of persons surviving into the lung-cancer age group who would, in previous eras, have died sooner and whose inherent resistance to lung cancer is lower than average

The impossibility is noted of measuring the extent to which any individual is exposed to atmospheric pollution, and studies of the different prevalence of lung cancer in large and in small towns are criticised Mr Todd concludes that nobody can say how far the estimates linking lung cancer mortality rates with smoking or with atmospheric pollution are applicable to the whole population

NEWS FROM KUALA LUMPUR

The Institute for Medical Research at Kuala Lumpur in Malaya has published a report on its work for 1955—a heartening document The list of papers covers work in microbiology, zoology, nutrition, and many other fields, and the collaboration between the institute and the U S Army Medical Research Unit continues to be fruitful

The work on malaria continues, "but at a lower ebb from the diversion of resources to the more challenging problems of filariasis" That the pressure of the attack on malaria can be slackened is an indication of its success The filariasis research unit, established in 1953, reports the discovery of sheathed microfilariæ in various local animals, but it is not yet known whether these are pathogenic to man Diethylcarbamazine has been given to carriers with success The same drug was given to the inhabitants of one kampong, while another kampong was sprayed with dieldrin, a *residual insecticide*, there was a striking decrease in the microfilaria rate and density in the drug treated population, but in neither was there any reduction in the proportion of mosquitoes infected

Much research has been done in virus and rickettsial diseases Volunteers were immunised against typhus by a live vaccine with appropriately timed doses of chloramphenicol 17 viruses (10 JE, 7 unidentified) have been isolated from 400,000 mosquitoes, and a dengue like virus was found to be responsible for a third of the undiagnosed fevers at Kuala Lumpur General Hospital

Research in nutrition includes the discovery of low thiamine levels in the milk of mothers of infants with acute respiratory disease, suggesting that the lack may reduce the infant's resistance to infection. Of 238 severely anæmic patients, most were found to be iron-deficient, and in many there was a superimposed megaloblastic anæmia Of 1200 patients whose stools were examined, hookworm infestation was much commoner in patients with a low hæmoglobin level, suggesting a cause for the high prevalence of iron deficiency

These examples give some idea of the impressive scope and quality of the work in progress in Malaya

EUROPEAN UNIVERSITY INTERCHANGE

A REPORT[1] by the Committee for Foreign University Interchange, whose chairman is Mr F W D Deakin, illustrates the value of university interchange as a means of promoting European understanding The 551 visits which have been arranged under the interchange scheme between this country and other European countries during the past eight years have produced a total of 985 contacts between the participating European universities In a foreword to the report, Sir James Mountford, vice chancellor of Liverpool University and chairman of the Universities Advisory Committee of the British Council, declares that the cumulative effect of these schemes has resulted in a "really impressive number of academic contacts," and that "the learned world owes a debt to the work that has been done"

The scheme for the interchange of short visits lasting one to three weeks by university teachers, which is administered with the help of the British Council, came into operation in 1948 between the United Kingdom and Belgium and has since been extended to include Austria, Finland, France, Germany, Iceland, Italy, The Netherlands, Norway, Portugal, Spain, Sweden, Switzerland, and Yugoslavia Each year 63 visits are made each way between these countries, and in the course of the current year there are plans to extend the scheme still further by the inclusion of Denmark, Turkey, and Poland.

The report describes a supplementary scheme, arranged between the United Kingdom, Belgium, France, Germany, and Yugoslavia, for assisting younger research workers to further their investigations by personal contact with others working in the same field abroad Belgium, France, Germany, and the United Kingdom also plan to introduce in the next academic session a new scheme for the exchange of longer teaching visits of one term or semester

In the field of postgraduate scholarships, 684 students from the Continent have been given awards by the British Council for study in the United Kingdom, whilst 549 British students have been helped by foreign governments or universities to study on the Continent The report also refers to the growing number of awards offered by such bodies as the Council of Europe, the High Authority of the European Coal and Steel Community, UNESCO, and NATO, and the interest shown by Western European Union in fostering coöperation between the universities of Europe

ELECTRICAL INCUBATORS

A REPORT to the East Anglian Regional Hospital Board[2] has drawn attention to the potential dangers of electrical incubators The report arose from a baby's death owing to overheating from an electrical fault, and it instanced several other cases where babies had been at risk

A draft British standard for electrically heated incubators and cots for babies has now been produced The adoption of this standard will eventually go far towards eradicating the dangers of incubators In fairness to the manufacturers it should be remembered that accidents have been extra ordinarily few, although in the past ten years very many babies have been nursed in incubators Trouble may some times have been due to lack of serviceing and overhaul, hospital attendants and junior nursing staff are not always as gentle as they should be when moving and cleaning incubators, and it seems likely that in some hospitals out of date amateur built incubators, and incubators made as proto types by firms not ordinarily engaged in building incubators, may still be in use These may be dangerous, and they should not be retained even for occasional use in a hospital where an incubator is rarely required

A GENTLEMAN'S LIBRARY

To buy books is always a pleasant hobby, to buy them for a definite purpose on a limited budget is also a skilled occupation Some fifty years ago Arnold Bennett in *Literary Taste* offered the man of modest means a useful guide to the books needed for a reasonably complete library of English literature His basic list included 562 volumes at a cost of £87 18*s* 6*d* In our more specialised (and expensive) days, Dr Iago Galdston, secretary of the medical information bureau of the New York Academy of Medicine, is seeking the help of his colleagues on both sides of the Atlantic in a more limited venture—though the cost will be about the same If you had no more than £80–90 to spend, what books, Dr Galdston asks, would you buy to form a modest working library on medical history? His putative readers have apparently studied only modern languages, for though the library may include books written in French, German, and Italian, he adds "We can count on very few who have a competence in either Latin or Greek" Lists of suggestions should be sent to Dr Galdston at the Academy, 2, East 103 Street, New York 29, N Y

NEW FILMS

Nutrition in Pregnancy (16 mm, sound, colour, 11 minutes, Great Britain, 1957) is designed to advise expectant mothers on diet both in the antenatal period and while breast feeding the baby

Emphasising that an adequate diet is the best foundation for the life of the baby, the film discusses the body's need of carbohydrates, fats, proteins, minerals, and vitamins and the foods that contain them The film consists of a talk illustrated throughout by animated diagrams Though well drawn, these tend to be fussy and the emphasis on dietary constituents is less helpful to a mother than suggested menus and recipes A lot of information is given in the film and this might have been better presented as an illustrated article or pamphlet.

The film is available free from the Nutrition Information Centre Vitamins Ltd, Upper Mall, London, W 6

Line of Defence, the third film of a series shown on B B C television recently, dealt with the international control of infectious diseases

A passenger from Asia where there has been a recent outbreak of smallpox, develops spots which though resembling those of chickenpox, are sufficiently atypical to make the ship's surgeon suspicious Through the World Health Organisation at Geneva, the port of London health authority is warned and the routine procedure on ship and ashore is shown. While the efficiency of the international organisation was well conveyed, the detail lacked balance such aspects as the differential diagnosis between variola and varicella by microscopy, egg inoculation and serum methods being shown at considerable length whereas the routine procedure as it affected the other passengers and crew of the ship was barely touched on.

THE LIVER

THE choice of subject for the second number of the *British Medical Bulletin* for this year[1] is timely in view of the many recent advances in our knowledge of the liver in health and disease The topics which have been selected for review cover a wide field, and will interest both physiologist and clinician

In his introduction, Sir Harold Himsworth, F.R S, emphasises that study of neither the normal alone nor the abnormal alone can supply the full information required for the comprehension of either Progress depends on our ability to integrate the knowledge gained on the two sides In the case of liver disease, the work which linked protein and fat metabolism with experimental liver injury was the stimulus which led to the development of much recent research In this respect, the article by J C Waterlow and G Bras on nutritional liver damage is especially interesting They point out that in man the only example of a direct effect of diet is the fatty liver of kwashiorkor In this condition recovery, both structural and functional, is the rule and earlier suggestions that the fatty change led on to cirrhosis cannot now be substantiated The rôle of protein deficiency in the development of permanent hepatic disease in underdeveloped countries is difficult to determine, but possibly malnutrition may have an indirect effect on the liver and predispose it to injury by other harmful agents

The place of protein in the dietary treatment of diffuse liver disease is becoming more clearly defined In acute hepatitis, J F Stokes and M L Rosenheim suggest an intake of about 100 g protein per day, and they remark that the advantages of a higher protein content are not clearly established In patients with ascites secondary to hepatic cirrhosis a high protein diet is often beneficial, provided that no neurological complications ensue The *mechanism* of the development of neuropsychiatric changes in liver failure is ably reviewed by Sheila Sherlock The condition depends on the absorption of nitrogenous material from the intestine, and in the acute stage it is essential to stop all dietary protein The liver has a remarkable ability to replace lost tissue, and the question of the stimulus to regeneration presents a fascinating and fundamental problem, which is discussed by R D Harkness Here again, protein may play a part, for there is some evidence that a fall in the protein concentration in the immediate environment of the hepatic cells may be responsible for setting in motion the regeneration of new tissue after partial hepatectomy Other features of protein metabolism are considered in several of the articles which make up this number In addition, many other aspects of hepatic function and disease are reviewed This admirable symposium can be recommended to all interested in recent progress in the study of the liver

University of Oxford

On June 8 the degree of D M was conferred on John Swithinbank

University of London

On May 22 the following degrees were conferred

M D—Eunice Lockey, John Newsome
M S—Kenneth Owen

Royal College of Surgeons of England

At a meeting of the council on June 13, with Sir Harry Platt, the president, in the chair, Lord Webb Johnson, past president, was admitted as a member of the court of patrons

The following were coopted to the council for the year 1957–58, representing various branches of practice

Dr John Hunt, general practice, Mr A C H Bell, gynæcology and obstetrics, Mr G Gill Carey, otolaryngology, Dr Frankis T Evans, anæsthetics, Mr A B Nutt, ophthalmology, Dr E Rohan Williams, radiology

The Hallett prize was awarded to Dr R Y Calne, of Guy's Hospital Medical School

A gift under covenant which will produce £45,000 was received from Cerebos Limited

Diplomas of fellowship were granted to the following

J W Garraway, W J L Harries, E J Hargadon M D Lord, W K M O Watkins, G R Benett, P S Watson, D H Nixseaman, George Kazantzis, B L Whitaker, M W F Dunning, H E D Griffiths, H B Eckstein P E Huddy, †R A Williams, P H E Courtenay Peter Goodall, J W Goodfellow, G P C Orlay, Katharine M Fussell, Ernest Kirz, C R Griffin, B T Hammond †R V Tracy Forster, Anant Charan, Gobindadas Goswami Anand Mohan Ahuja, †G O Clark, Muneer Husain, N K G Mendis, †R K Roddie, D D Beard, J H Hodgson, A R Kirby, Mary K Marchant †A W Morrison, Mihir Kumar Senapati, C V Wijesinha, J A Wilkinson, Nabil Ahmed Allouba, A G Bond, †B W M Bushell Abdul Karim Chaudhry, Hansa Deva Perera Goonatillake, G A D Lavy, B K Madden, Arivaman Mahanama Mendis, Bernard Nolan, G J Smart, Oliver Wesley James, Elliott Bader Ranjit Basu, R G K de Castro, M H Flint, J R W Gleave, *P A Graham, Syed Zafar Haider, C D Levis, I J MacQueen, Salil Kumar Mukhopadhyay, Durgadas Sengupta Dhirajlal Chhelshanker Vora, B M Andrea, Shyam Kishinchand Bulchandani, Kedarnath Vasudeo Chaubal Harold Collinson, K B Cornwell, †Israr Hasan Jafri, Adrian Litton, J R McQuaide G M Nunn, *Ramachandra Pararajasegaram, Rasikbhai Ambalal Patel, J P Richardson, A G G Robson, Norman Samuels, Brahma Dutt Sharma, Kedar Nath Sharma Thomas Stack, Henry Sunderland, J G Sweeney Cyril Toker, R O Wise, F C O Allen J R Badger K S Brearley, *Madhav Ranchandra Chaudhary*, H J Done H L Duthie W J Eskdale, R K Greenwood, R S M Ling, D C Mackenzie, B R Meyerowitz, J F Newcombe Ishwarbhai Chaturbhai Patel, V M Rao, Fardoon Phiroze Soonawalla, D W Whiteway C A Cass, Jean A Evans, †V T Hammond N J Jackson, P R Knight Peter Knipe, A B Oliveira, Ratan Chandra Varma John Ludbrook

* In ophthalmology † In otolaryngology

A diploma of membership was granted to M B Rees Jones

Royal College of Physicians of Ireland

At a meeting of the college on June 7 with Dr F J O Donnell, the president, in the chair, the following were admitted to the fellowship

W A Gillespie M E Cheffins, J D Kennedy D J O'Callaghan, and H B Kelly (*in absentia*)

The following were admitted as licentiates and members

J P Alexander Thomas Haran, B J Lomass and J R McCarthy

National Institute of Mental Health, Washington

Dr J J Elkes is resigning the chair of experimental psychiatry in the University of Birmingham on his appointment as head of the clinical neuropharmacology research centre of this institute

Lebanon Hospital

The annual meeting of this hospital will be held on Thursday, July 4, at 5 P M, at the Cora Hotel, Upper Woburn Place, London, W C 1 The Earl of Feversham will be in the chair, and the speakers will include Prof Alexander Kennedy

Biochemistry Society

A meeting of this society will be held in the department of chemistry of King's College, Newcastle upon Tyne, on Friday, June 28, at 11 15 A M On Saturday, June 29, at 11 A M the society will hold a joint meeting with the *Association of Clinical Biochemists* when the programme will include a symposium on mucoproteins

Oxford Graduates' Medical Club

The summer dinner of this club will be held in Trinity College, Oxford, on Friday, July 5, at 7 30 P M, when Dr Maurice Campbell will be in the chair Members may bring medically qualified guests of either sex Tickets (37*s* 6*d*) may be had before June 28 from Dr Ronald Macbeth, department of otolaryngology, Radcliffe Infirmary, Oxford

Service Awards

On the occasion of the Queen's birthday, in recognition of distinguished services in the Near East, October to December, 1956, the following doctors received awards

M C—Captain John Malcolm Elliott, M B Birm, R A M C
Mention in despatches—Surgeon Lieutenant John Gwythar Bradford, M B Lond, R N, 45 Commando, Royal Marines, Surgeon Lieutenant Peter Gordon Harries M B Lond, R N, H M S *Diana*

Lady Tata Memorial Fund

For research on leukæmia and allied diseases, in the year beginning October, the trustees of this Fund have made the following awards

Grants for Research Expenses—Dr J Kieler (Denmark) Fibiger Laboratory, Dr M Seligmann (France), Institute Pasteur Dr M Simonsen (Denmark), Fibiger Laboratory, Dr B Thorell (Sweden), Karolinska Institute, Dr G Klein (Sweden), Karolinska Institute, and Dr M. Bessis (France), Centre National de Transfusion Sanguine

Scholarships—Dr G Marinone (Italy), University of Pavia and Dr A J Therkelsen (Denmark), Institute of General Pathology

Scholarship and Grant—Dr G V Seaman (England) Department of Colloid Science, Cambridge

Ross Institute of Tropical Hygiene

At a luncheon held at the London School of Hygiene and Tropical Medicine on June 12 to mark the centenary of Sir Ronald Ross's birth, Sir Eric Macfadyen, the chairman, recalled that the establishment of the institute named after Ross was mainly due to the efforts of the late Sir William Simpson and the late Sir Malcolm Watson, and Austin Chamberlain had been mainly responsible for the institute's incorporation with the London School of Hygiene and Tropical Medicine Dr M G Candau, director general of W H O, spoke of the Organisation's debt to Ross, who, forty five years before the introduction of D D T, established the principles that were now being followed in programmes of malaria eradication In May, 1955, W H O had decided to support steps towards achieving world wide eradication of this disease By the end of March this year 63 countries and territories had accepted eradication as a goal, in 10 this had been almost achieved, while in 15 the work was well advanced Mortality and morbidity attributable to malaria were now at levels not more than a third of those twelve years ago when the attack with residual insecticides was begun Prof G Macdonald, director of the institute, recalled that it was Dr Candau's powerful advocacy which led the World Health Assembly in 1955 to decide on a policy of eradication Turning to the work of the institute, he said that this comprised advisory and consultative services, teaching, and research Research was being directed towards the reasons for the prevalence of malaria, and the resistance of anopheles to insecticides

---

On June 10 Prof J H Burn F R S, received the honorary D SC of Yale University

CORRIGENDUM *Harvey Tercentenary*—In our report last week (p 1237) of the Harvey Tercentenary Conference we misrepresented Prof K. J Franklin's remarks Fabricius of Padua first noticed that valves are a feature of many (not *all*, as we stated) veins of the body in 1574, his book, however, was not published until 1603 Harvey *was* a fellow of the College of Physicians of London The epithet "Royal" was not added until towards the end of the 17th century, and then far from invariably

HÆMOLYTIC DISEASE OF THE NEWBORN

DEATHS IN ENGLAND AND WALES DURING 1953 AND 1955

W. WALKER *
M.D. Durh.
LECTURER IN CHILD HEALTH IN THE UNIVERSITY OF DURHAM

P. L. MOLLISON
B.A., M.D. Camb., F.R.C.P.
DIRECTOR, BLOOD TRANSFUSION RESEARCH UNIT, MEDICAL RESEARCH COUNCIL

From the Children's Department, Royal Victoria Infirmary, Newcastle upon Tyne, and the M.R.C. Blood Transfusion Research Unit, Postgraduate Medical School of London

THE increasing use of exchange transfusion has reduced the number of deaths from hæmolytic disease, but over the country as a whole the reduction has been less than was expected.

The correct use of exchange transfusion enables more than 95% of infants with hæmolytic disease to survive if born alive (Allen et al. 1950, Walker and Neligan 1955), whereas with simple transfusion only about 80% are likely to do so.†

Assuming that 1 in every 200 infants will have hæmolytic disease, and that 15% of affected infants will be stillborn, one can calculate the expected mortality under different régimes of treatment among those born alive: it is 0.85 per 1000 live births when simple transfusion is used but less than 0.2 when exchange transfusion is used exclusively.

Fig. 1 shows the changing mortality from hæmolytic disease over the past twenty-one years as recorded in the Registrar-General's Statistical Review.

In 1935–41 serological tests for hæmolytic disease were not available: this explains why the number of deaths ascribed to hæmolytic disease of the newborn is about half the number expected. From 1942 onwards the number of deaths registered as due to hæmolytic disease of the newborn rises steadily to almost 0.8 per 1000 live births in 1945–51, a level approaching that expected if simple transfusion alone was being used. A small part of this rise may be due to the greater number of women immunised by transfusion, after blood became more readily available from 1940 onwards.

The first year in which a definite decrease in mortality can be discerned is 1952. Although Diamond first described his method of exchange transfusion in 1947 and this method was used in some hospitals in England from then onwards (Mollison and Cutbush 1948, 1949), many hospitals were still using simple transfusion as late as 1952. In that year the results of a controlled trial comparing simple and exchange transfusion in many different centres in England, Wales, and Ireland were published (Mollison and Walker 1952) and this was followed by a more widespread use of exchange transfusion in England. Nevertheless in 1953 the reported mortality from hæmolytic disease of the newborn was 0.6 per 1000 live births—i.e., three times what would be expected if all severely affected infants were being satisfactorily treated by exchange transfusion.

In the face of this it was clearly desirable to study the circumstances of every death certified as due to hæmolytic disease to try to discover why the death-rate remained disappointingly high.

Method of Inquiry

Copies of the death certificates for all infants certified as dying from hæmolytic disease of the newborn in 1953 and 1955 were made available through the Registrar-General's Office, London.

TABLE I—CAUSES OF DEATH IN INFANTS REGISTERED AS DYING FROM HÆMOLYTIC DISEASE OF THE NEWBORN

—	1953		1955	
Due to H.D.N.		312		315
Not due to H.D.N.				
Kernicterus of prematurity	53	97	41	85
Non-hæmolytic hydrops	11		11	
Miscellaneous	33		33	
Not traced		2		0
Total registered as due to H.D.N.		411		400

A circular letter was sent to the doctor who had signed each certificate to explain the purpose of the inquiry, and a form was enclosed asking for the following data:

(1) The sex and birth weight of the infant.
(2) Its age on admission to hospital (if not born in hospital).
(3) The serological findings in mother and infant, including the result of antenatal tests.
(4) The cord-blood hæmoglobin and bilirubin levels.
(5) The time of onset and degree of jaundice.
(6) Details about any transfusions given.
(7) The clinical course of the disease and mode of death.
(8) The age at death.
(9) The necropsy findings.

In many cases the hospital notes were borrowed and, if necessary, letters were written to the pediatrician, pathologist, or family doctor, asking for more detailed information.

Data were obtained for 409 of 411 deaths registered in 1953 and for all 400 registered in 1955. (The number of liveborn infants was 684,000 in 1953 and 668,000 in 1955.)

Results

DEATHS NOT DUE TO HÆMOLYTIC DISEASE OF NEWBORN

At an early stage of the inquiry it became clear that many infants were certified as having died from hæmolytic disease of the newborn whereas in fact they had died from other causes (table I).

The commonest "other cause" was kernicterus of prematurity—i.e., kernicterus in a premature infant without any hæmatological or serological evidence of hæmolytic disease of the newborn. This condition was

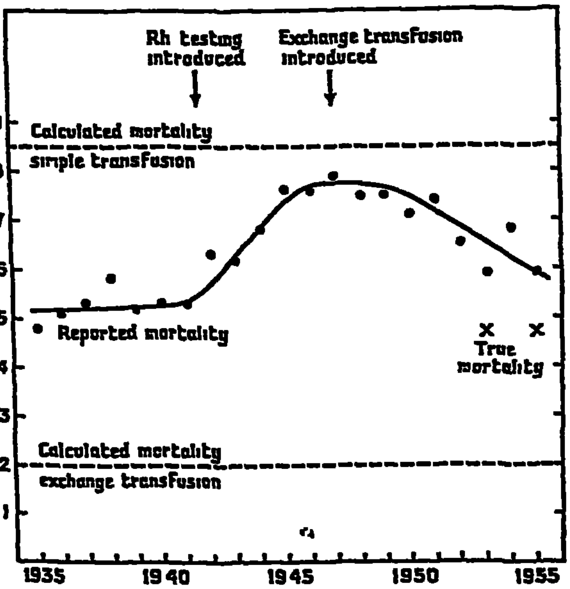

Fig. 1—Mortality from hæmolytic disease of newborn from 1935 to 1955. 'Reported mortality' is as reported to Registrar-General. Corrected figures for 1953 and 1955, based on the present investigation, are marked 'True mortality'.

---

* Aided by a grant for secretarial help from the Scientific Research Committee of the Newcastle Regional Hospital Board.

† This figure is calculated from the data of Armitage and Mollison (1953) applied to the series of Mollison (1956, p. 464, table XXXV). According to these figures the calculated mortality with simple transfusion alone is 17%.

TABLE II—DEATHS DUE TO HÆMOLYTIC DISEASE OF THE NEWBORN

Cause of death	1953		1955	
Solely H D N				
Hydrops fœtalis		40		29
Heart failure	58		55	
Kernicterus	105		82	
Exchange transfusion	28	239	60	242
Late anæmia	4		1	
Other causes	44		44	
Important contributory factors		33		44
Total		312		315

recognised only after the publications of Aidin et al (1950) and Zuelzer and Mudgett (1950) Probably its increasing recognition in recent years has masked a slight fall in the number of deaths from hæmolytic disease of the newborn because, up to the end of 1955, deaths from kernicterus, from whatever cause, were recorded as due to hæmolytic disease of the newborn Similarly, all cases of hydrops fœtalis were recorded as due to hæmolytic disease of the newborn, whereas each year a number occurred where a diagnosis of hæmolytic disease was not supported on pathological grounds or had been excluded serologically In others—e g , some infants who had died from hæmorrhagic disease of the newborn—there was no evidence to justify the recorded diagnosis of hæmolytic disease , indeed in many this diagnosis had been excluded by serological tests

The 182 deaths not due to hæmolytic disease of the newborn will not be considered further here

CAUSES OF DEATH IN INFANTS WITH HÆMOLYTIC DISEASE

In 87% of the 627 cases in which death was attributed to hæmolytic disease of the newborn, full serological confirmation of the diagnosis was obtained 69% of the 627 cases were predicted antenatally, 3% were first recognised because of tests on cord blood, and in 15% serological confirmation was obtained postnatally after hæmolytic disease had been diagnosed clinically In the remaining 13% diagnosis rested mainly on clear-cut clinical and pathological evidence, although in some cases the Coombs test had been found to be positive at some time

In table II the 627 deaths have been subdivided into those due solely to hæmolytic disease of the newborn and those in which there were other important contributory factors An attempt was made to answer the question "Would the child have died if there had been no hæmolytic disease ?" If the answer was "Probably not," hæmolytic disease of the newborn was regarded as the sole cause of death These cases were then further subdivided into the categories shown in table II

Apart from the cases of hydrops fœtalis, among the deaths due solely to hæmolytic disease of the newborn, heart failure, kernicterus, and exchange transfusion accounted for 388 of the 481 deaths

Hydrops Fœtalis

69 deaths were stated to have occurred in hydropic infants born alive , 49 of these were in extremis at birth and died within an hour , 18 more died in the first nine hours , and 2 survived until the second day None who survived more than an hour were grossly œdematous, but all were very anæmic and should probably have been classified as having very severe hæmolytic disease rather than hydrops Only 3 were treated by exchange transfusion, and all died during the transfusion

Heart-failure

In many cases the diagnosis of heart failure was made by the clinician in charge of the case , in others it was deduced from the recorded observation of severe anæmia leading to death on the first day of life , occasionally it was based on necropsy findings Some infants who died during exchange transfusion were considered to have died from heart failure, present before transfusion, and these deaths have been included in the heart failure group and not among the deaths due to exchange transfusion

Only 75 of the 113 infants who died from heart-failure were treated by exchange transfusion, and only 66 of these within the first nine hours of life

Of the 75 in whom exchange transfusion was attempted, 57 died during the transfusion, and in many of these it seemed probable that the immediate cause of death was failure to remove more blood than was injected In fact, in 30 cases more blood was injected than withdrawn, and in 18 cases equal volumes were exchanged

The severe nature of hæmolytic disease in this group is shown by the observation that in two thirds of the cases in which the cord hæmoglobin was recorded it was less than 9 g per 100 ml Hæmolytic disease was predicted antenatally in only 88 of the 113 cases in this group, and 22 were recognised because of clinical evidence of very severe disease 26 of these infants were admitted to hospital only after birth

Kernicterus

Kernicterus accounted for 105 deaths in 1953 but for only 82 in 1955—a fall possibly associated with an increased use of exchange transfusion However, this fall was offset by the greater number of deaths during or soon after exchange transfusion in 1955, compared with 1953 In 151 cases, the diagnosis of kernicterus was based on post mortem findings, but in a few it was deduced from the clinical picture of cerebral damage during the first week of life in a deeply jaundiced infant without other apparent cause

Of the 187 infants who died from kernicterus, only 60% were born in the hospital where they received treatment In this group, failure to predict hæmolytic disease or to recognise it soon after birth seems to have been the cause of at least 41 deaths , for, in 31 cases kernicterus was already present when treatment was first considered, and in 10 others the infant was so deeply jaundiced that transfusion was not considered worth while

Cord-hæmoglobin levels were determined in 77 cases and were above 15 g per 100 ml in 30 of these , only 2 of these 30 infants had been treated by early adequate exchange transfusion (defined as more than 50 ml per lb body weight on the first day of life)

Cord bilirubin levels were determined in only 29 cases , in 3 the level was below 3 mg per 100 ml but in 19 it was above 5 mg

Of the 187 infants who died from kernicterus, exchange transfusion was attempted in only 64 , in 9 of these the operation failed completely , in 14 cases less than 40 ml , and in 13 cases between 40 ml and 60 ml of blood per lb body-weight was exchanged , in 4 other cases the volume was not recorded Thus in only 24 of the 187 cases was a relatively large exchange transfusion (more than 60 ml per lb) given

Exchange Transfusion

In table II deaths have been classed as "associated with exchange transfusion" only when they occurred during or within four hours of exchange transfusion, where the "immediate" cause was not clear but when it seemed, from the information available, that death would not otherwise have taken place at that time 50 other infants died during or shortly after exchange transfusion but have not been included because they might well have died without exchange transfusion 36 were already in heart failure , 3 others were moribund owing to kernicterus when transfusion was undertaken , and 11, when transfusion was begun, were already very ill because of severe hæmolytic disease or some complicating factor such as cerebral hæmorrhage

The number of deaths ascribed directly to exchange transfusion was 28 in 1953 and 60 in 1955 Among these 88 infants were 37 who were seriously ill at the time of transfusion (27 of them had cord-hæmoglobin levels below 9 g per 100 ml), but this leaves 51 infants whose condition was quite good (7 had cord-hæmoglobin levels above 14 8 g) Two-thirds of the deaths attributed to exchange transfusion took place before 60 ml per lb body-weight had been exchanged, but death was not related to the infant's age at the time of transfusion

Late Anæmia

In this series only 5 deaths were due to late anæmia—i e , anæmia recognised for the first time towards the end of the first week of life or later in an infant not seriously ill at birth All had hæmoglobin values below 5 g per 100 ml at the time of admission, and jaundice was never marked in any

Other Causes

The category "other" in table II refers to cases in which the available evidence suggested that death was due to hæmolytic disease or to the treatment given, but clinical and pathological records were incomplete or otherwise unsatisfactory.

"Important Contributory Factors"

Contributory factors were regarded as important when the degree of hæmolytic disease seemed insufficient to account for death In some instances it was easy to decide that a particular case fell into this category—e g , when an infant with mild or adequately treated hæmolytic disease had a severe congenital defect In others it was more difficult—e g , when an infant with moderately severe hæmolytic disease had a cerebral birth injury The 77 infants in this group included 11 with severe congenital defects , 18 with cerebral hæmorrhage , 11 with pneumonia, of whom 7 died in the first four days of life and the remainder at periods up to the age of two months , 23 premature infants, of whom 8 weighed less than 3 lb , and 7 weighed 3–4 lb , 8 whose death was due to maternal causes or associated with delivery , and 6 with miscellaneous conditions

MANAGEMENT OF HÆMOLYTIC DISEASE OF NEWBORN

Various analyses were made of the way in which the diagnosis was reached and the treatment was given The 69 cases of liveborn hydrops were excluded because this condition is rarely if ever compatible with survival On the other hand, cases in which there were thought to be "important contributory causes" of death were included because it was only in one or two isolated instances that the "contributory cause" modified the conduct of the case

Prediction and Recognition of Hæmolytic Disease

In table III the cases have been subdivided according to the manner in which the diagnosis was first made

Thus, of the 558 cases, 404 were diagnosed serologically, usually because antibodies had been detected antenatally but occasionally because cord blood taken routinely had given a positive Coombs test The remaining 154 were diagnosed clinically—149 because of deep jaundice or other evidence of severe disease, and 5 because of anæmia developing towards the end of the first week of life or later

TABLE III—AGE ON ADMISSION TO HOSPITAL IN RELATION TO METHOD OF DIAGNOSIS

Diagnosis	No of cases	Born in hospital	Age on admission to hospital			Never admitted
			First 12 hr	12–24 hr	After 1 day	
Serological	404(72%)	363	23	6	10	2
Clinical	154(28%)	27	29	11	71	16
Total *	558	390(70%)	52(9%)	17(3%)	81(15%)	18(3%)

* 69 cases of hydrops in babies born alive are excluded from this analysis

Of the 404 infants whose disease was diagnosed serologically, 363 were delivered in hospital and 29 were admitted within the first day of life Only 12 were admitted after the first day or not at all Of the 154 whose disease was diagnosed on clinical grounds only 67 were born in hospital or admitted within twenty-four hours

The clinically diagnosed cases can be subdivided into four approximately equal groups depending on the features that led to the recognition of hæmolytic disease those with signs of severe disease—e g , anæmia, jaundice, bruising, and œdema—within eight hours of birth , those in which jaundice appeared between eight and twenty-four hours of birth , those in which the diagnosis was made only because of intense jaundice during the first week of life , and those recognised only when signs of brain damage called attention to the diagnosis

Of the 558 infants under discussion, 289 were jaundiced within eight hours of birth and a further 95 within twenty-four hours Of the 174 who did not develop jaundice in the first twenty-four hours, 78 died within eight and 35 others within twenty-four hours of birth Thus only 61 infants (11%) survived more than a day without becoming jaundiced, and even then a quarter of those died from causes other than hæmolytic disease

In our opinion, 108 deaths could be partly attributed to failure to predict disease and 58 others to failure to recognise clinical evidence early

Failure to predict hæmolytic disease was very seldom due to the fact that the blood-group factor concerned was not Rh (D) In only 11 cases was disease due to some other incompatibility 8 were examples of incompatibility within the ABO blood group system, 2 were due to anti-c, and 1 to anti-E

TABLE IV—TREATMENT IN RELATION TO METHOD OF DIAGNOSIS

Diagnosis	No of cases	Exchange transfusion		Simple transfusion		No transfusion
		First day	Later	First day	Later	
Serological	404(72%)	268	7	33	16	80
Clinical	154(28%)	30	16	6	18	84
Total	558	298(54%)	23(4%)	39(7%)	34(6%)	164(29%)

Of the cases in which Rh (D) was concerned, only 2% of the failures to predict the disease were due to technical errors In the rest, failure to predict hæmolytic disease was due to the fact that adequate antenatal tests had not been made One surprising finding was that, in half the cases diagnosed only on clinical grounds, full serological tests were never carried out, even after delivery , hence the diagnosis was not proved, nor could any reliable prognosis have been given

It is evident from these various observations that failure to predict the disease was due chiefly to omission of antenatal serological tests rather than to any failure in the tests themselves

Treatment in Relation to Timely Diagnosis

Table III shows that 390 (70%) of the infants who died were born in hospital, and 52 (9%) were admitted within twelve hours of birth It is therefore evident that failure to recognise the disease early, although contributory in some cases, was not responsible for the majority of deaths

In table IV the cases have been divided in the same way as in table III but in relation to treatment

Of the infants whose disease was diagnosed serologically 66% were treated by exchange transfusion on the first day of life , but 20% received no treatment whatever, although almost all were born in, or admitted to, hospital within twelve hours of birth

Of those whose disease was diagnosed because of the development of clinical signs of the disease, only 31%

were treated by exchange transfusion and 54% received no treatment

In 1955, 202 infants had been treated by exchange transfusion, compared with 119 in 1953 Even so, 84 infants who died in 1955 and 153 who died in 1953 had not received exchange transfusion indeed, in the two years 164 infants had received no treatment at all

The fact that 321 died despite exchange transfusion calls for separate comment

Details of Exchange Transfusion

Of the 321 exchange transfusions, 258 were given within the first nine hours and 63 later Analyses of the amounts of blood exchanged showed no difference between these two groups or between the two years All the cases have therefore been considered together, and the amounts exchanged are shown in fig 2 In the cases in which exchange transfusion had been given or attempted only 34% of the babies received more than 60 ml per lb body-weight, 21% received 40–60 ml per lb, 22% received 20–40 ml per lb, and 11% less than 20 ml per lb In 12% the precise amount exchanged was not recorded, in half of these the amount was probably trivial

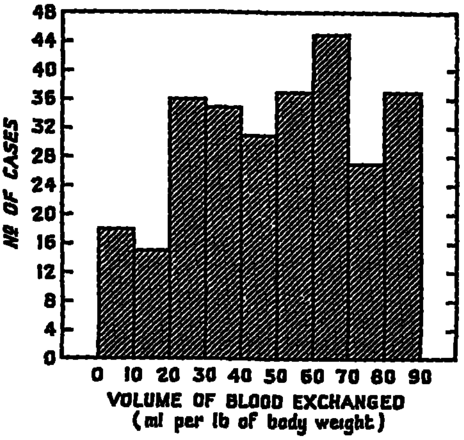

Fig 2—Volume of blood used in 281 of 321 cases in which exchange transfusion was attempted (volume used in remaining 40 cases was not recorded)

The amounts of blood injected and withdrawn were about equal in most cases In 56 infants with cord-hæmoglobin levels below 9 g per 100 ml it seems possible that failure to withdraw considerably more blood than was injected contributed to the infant's death Thus, in 37 of the 56 cases the amount injected was equal to, or greater than, the amount withdrawn, in the remaining cases the amount withdrawn was only slightly (10–20 ml) greater than the amount injected Many of these infants died during the transfusion but have been included among the deaths due to heart-failure rather than in those "associated with exchange transfusion"

In a few cases in which there did not seem to be any clear indication for removing more blood than was injected it appeared that this had contributed to the infant's death Thus in a case where the infant had a cord-hæmoglobin level about 15 g per 100 ml, 70 ml more blood was removed than was injected, and this seemed to precipitate collapse and death during transfusion

The time after birth at which exchange transfusion was performed varied from an hour to six days, but in 80% of cases it was less than nine hours In 33 cases failure of exchange transfusion was probably due to its being undertaken too late Among these were 4 very anæmic infants who were treated within the first nine hours of life but whose condition had much deteriorated between birth and transfusion

The technique of exchange transfusion seemed to have contributed to 28 of the deaths For example, in 5 the umbilical vein was perforated and a large amount of blood was found free in the peritoneal cavity at necropsy, and in 2 others umbilical thrombophlebitis, associated with a staphylococcal septicæmia and lung abscesses, was found at necropsy The time taken for exchange transfusion varied from nineteen minutes in one case to nine hours in another, and in 9 cases the rate at which the transfusion was given apparently contributed to death

Repeated exchange transfusion had been attempted in only 22 infants, all of whom had been born in hospital (6 in 1953 and 16 in 1955)

Tests on Cord Blood

A Coombs test on cord blood was performed in 67% of the cases in 1953 and 78% in 1955, these percentages are very similar to the proportion of cases in which the disease was predicted antenatally in those years Only 5 false negative results were recorded in the two years

Cord hæmoglobin levels were recorded in 50% of the cases in 1953 and 65% in 1955, the plasma bilirubin level of cord blood was recorded in 14% of cases in 1953 but in 40% in 1955

40% of all cord-hæmoglobin levels were below 9 g per 100 ml, 44% were 9 0–14 8 g, and 16% were above 14 8 g

Influence of Previous Obstetric History on Method of Treatment

Exchange transfusion was used in 70% of cases in which a previous infant in the family had been affected, compared with 54% where no previous infant had had hæmolytic disease Even so, 24% of infants preceded by affected siblings were allowed to die untreated There was no obvious relation between the use of exchange transfusion and the number of affected siblings or the severity of disease in these It was surprising that 8 of the 14 infants preceded by stillbirth due to hæmolytic disease did not receive exchange transfusion, in fact 5 received no treatment at all

ANALYSIS ON BASIS OF AGE AT DEATH, BIRTH-WEIGHT, AND SEX

Of the 558 infants, 275 died on the first day of life, mostly from heart-failure or during exchange transfusion, and 224 died between the second and fifth days, mainly from kernicterus 57 died later In 2 cases the time of death was not recorded

The birth-weight of 48 was not recorded but 104 (20%) of the remainder weighed $5^1/_2$ lb or less 63 had been born prematurely spontaneously and 41 by premature induction The birth-weight distribution in the two years was practically identical, and no correlation between birth-weight and cause of death was found except that in some cases prematurity was regarded as an important contributory factor

In both years there was a preponderance of males among the fatal cases, the ratio being 1 4/1 in 1953 and 1 1/1 in 1955 In table v the cases have been analysed by sex in relation to the main causes of death

TABLE V—SEX AND CAUSE OF DEATH

Cause of death	Male	Female	Sex not recorded	Ratio
Hydrops fœtalis	32	37	0	0 86
Heart failure	48	62	3	0 78
Exchange transfusion	41	45	2	0 91
Kernicterus	127	59	1	2 1
Miscellaneous	87	74	9	1 2
Total	335	277	16	1 2

The only difference between the sexes as regards the cause of death is that, among the infants dying with kernicterus, males were twice as common as females—a difference which is statistically significant (cf Diamond et al 1950 and Armitage and Mollison 1953) The preponderance of males developing kernicterus was greater in 1953 (75/29) than in 1955 (52/30) A possible explanation is that exchange transfusion was being used less in 1953, and that therefore more deaths from kernicterus took place in that year

There is a slight preponderance of females in the other groups of cases, but this is not significant

Discussion

One of the first findings in this inquiry was that many infants dying from other conditions were being registered as having died from hæmolytic disease of the newborn, which disease in fact accounted for only about 75% of the number certified Most of the deaths wrongly included were due to "kernicterus of prematurity" When this became apparent, the Registrar-General was informed, and he agreed that in future this condition should be certified separately from hæmolytic disease of the newborn

It is, of course, possible that some infants dying of hæmolytic disease of the newborn were being certified as dying from other causes The finding that so few infants were recorded as dying from anæmia after the first few days of life suggests that in some cases of this kind hæmolytic disease of the newborn may have been overlooked

Even when deaths not due to hæmolytic disease are excluded, the deaths are at least three times as numerous as would be expected with modern treatment There appear to be two main causes for this (1) failure to predict the disease before birth or to diagnose it sufficiently soon after birth, and (2) failure to attempt an exchange transfusion or to perform it satisfactorily

If early diagnosis is essential to the correct management of hæmolytic disease, antenatal prediction gives the infant its best chance This chance was denied to 168 of the 558 non-hydropic infants who died of hæmolytic disease Failure to predict disease was due to the presence of antibodies other than anti-Rh (D) in only 11 instances and to technical error in only 5 It is therefore clear that failure to predict hæmolytic disease almost always resulted from failure to carry out the necessary tests

The significance of early clinical features was not always appreciated Thus 87 infants, although clinically affected within the first twenty-four hours, were not admitted until after this time indeed 31 were not diagnosed until kernicterus had developed Early jaundice, present in more than 90% of the fatal cases, often failed to suggest the true diagnosis and the possible need for immediate exchange transfusion

There is little doubt that exchange transfusion should be given to all severely affected infants, for this is the only method of treatment which will overcome heart-failure in the very anæmic infants and prevent deep jaundice and kernicterus in the others Since the present inquiry deals only with fatal cases, it can be assumed that most of the infants should have received exchange transfusion, yet 80 of the 404 in whom the diagnosis was made serologically died untreated, and 49 received only simple transfusion 164 (29%) of the infants who died had not been transfused, and 73 (13%) had received simple transfusion Simple transfusion was used on the first day of life in 39 cases although only a third as much in 1955 as in 1953, but it is very doubtful whether simple transfusion is ever justified where treatment on the first day is needed In 52 cases premature labour had been induced in an effort to mitigate the severity of the disease, yet 17 of 45 non hydropic infants were not treated by exchange transfusion Similarly, 21 of 74 infants received no treatment even though a previous infant in the family had died from hæmolytic disease of the newborn or had been stillborn from this cause

321 infants (58%) were treated by exchange transfusion, among the infants admitted after the first day of life the proportion treated by exchange transfusion was lower (23 out of 81) There is little doubt that exchange transfusion should have been given to more of the infants who were deeply jaundiced on admission, for the transfusion can usually be performed by the umbilical route without difficulty up to the age of five or six days It could similarly be claimed that repeated exchange transfusion was not given as often as was indicated Of the 187 cases of kernicterus, 124 were not treated by exchange transfusion, and of the 63 where this was attempted, it failed completely in 8, while in 31 the amount of blood exchanged was less than 60 ml per lb body-weight

Although the majority of the cases had been treated by exchange transfusion, the amount of blood exchanged was too small in many cases, for in 121 the operation either failed completely or exchanged less than 40 ml per lb body-weight This, together with the finding that many infants died during the transfusion, suggests that the operation may not always have been carried out as well as it might have been In a third of the cases the balance between the volume of blood injected and withdrawn was incorrect, for some very anæmic infants received more blood than was withdrawn, and in others the amount withdrawn was no greater than the amount injected It is possible that citrate toxicity may have played a part in other deaths, but no information on this point was available

It seems that there is an increasing awareness of the value of estimating the hæmoglobin and bilirubin levels in cord blood certainly these estimates were made more often in 1955 than in 1953

The inadvisability of using the cord-hæmoglobin level as the sole criterion of severity is shown by the observation that 16% of all the cord-hæmoglobin levels were above 14·8 g per 100 ml, and that, among the cases of kernicterus, as many as 30 out of 77 (40%) of the recorded levels were over 15 g Of these 30, only 2 were treated by early adequate exchange transfusion

The incidence of kernicterus in mature infants with hæmolytic disease of the newborn with a cord-hæmoglobin level above 15 8 g per 100 ml is low (5%) without exchange transfusion (Armitage and Mollison 1953) Because of this known relationship, treatment is often withheld from mature infants when the cord-hæmoglobin level is found to be over about 15 g It has long been clear that, although a high cord-hæmoglobin level is a very favourable prognostic sign, exchange transfusion should still be given if more than a trace of jaundice develops within the first twenty-four hours of life

Although exchange transfusion is not a difficult operation, the best results are to be expected in hospitals where the staff treat a large number of cases and gain considerable experience The deaths investigated were distributed among 244 hospitals (172 in 1953 and 165 in 1955) Even if all cases of hæmolytic disease of the newborn were treated in these hospitals alone, the average yearly number in each would have been about 12, of which only about 8 would have needed exchange transfusion Since it is known that some hospitals have far more than others it is evident that in some the number of cases of hæmolytic disease treated must be very small indeed

Summary

The clinical records of all infants certified as dying from hæmolytic disease of the newborn in England and Wales during 1953 and 1955 have been examined

In each of the two years about 400 infants were certified as dying from hæmolytic disease of the newborn However, owing to the definition of hæmolytic disease of the newborn for the purpose of certification, the label was often attached to infants dying from other conditions such as "kernicterus of prematurity," and the true number of deaths from hæmolytic disease of the newborn was about 310 in each of the two years

Factors contributing to the deaths from hæmolytic disease were failure to predict the disease antenatally,

failure to recognise early clinical evidence of the disease, and failure to give adequate exchange transfusion

Attention is called to the fact that the treatment of hæmolytic disease of the newborn is undertaken at a very large number of hospitals In many of these the number of cases seen is very small, and it is therefore impossible for the staff to gain the necessary experience and familiarity with this condition

It is suggested that, if all cases of hæmolytic disease of the newborn (due to anti-Rh (D)) were predicted antenatally and were treated when necessary by early adequate exchange transfusion, the present death-rate could be greatly reduced Each year, in England and Wales, more than 150 infants would be saved

We are most grateful to Dr G E Godber, of the Ministry of Health, and to Dr W D P Logan, of the Registrar-General's department, for making this study possible We are also greatly indebted to the numerous doctors throughout the country who so readily put their clinical records at our disposal

MONGOLISM AND OTHER CONGENITAL ABNORMALITIES

AN EPIDEMIOLOGICAL STUDY IN NORTHAMPTONSHIRE

M J PLEYDELL
M C , M D Lond , D P H.
DEPUTY COUNTY MEDICAL OFFICER OF HEALTH, NORTHAMPTONSHIRE

THIS investigation was undertaken because I noticed that in Northamptonshire mongol children seemed to be born in groups in different areas at different times The findings suggest that mongolism and other congenital abnormalities may be more closely related to maternal infection than has hitherto been supposed

Sources of Information

The information regarding the births of children with congenital abnormalities was obtained as follows

(1) A search was made of the mental deficiency records of the mental health department and the handicapped pupils register of the school health service department of the local health authority

(2) With the coöperation of the consultant pædiatricians, a search was made of their records *of the congenital abnormalities* referred to them

(3) All the health visitors and midwives of the local health authority were asked about births of children with congenital abnormalities in their areas, and where the mothers were living throughout the pregnancies

(4) A search was made of the hospital birth registers and the infant mortality records

(5) Further information about cases of hare lip and cleft palate was found in the records of the consultant surgeons serving the area, the school dental department, the hospital consultant dental officer, and the speech therapists of the local health authority

Where there was more than one abnormality the case was classified under the more serious defect Thus mongols with congenital heart disease or cleft palate were classed as mongols Cases of anencephaly with spina bifida were classed under anencephaly Cases of spina bifida and hydrocephalus were classed under spina bifida

TABLE I—BIRTHS OF INFANTS WITH CONGENITAL ABNORMALITIES IN NORTHAMPTONSHIRE, 1944–55

Year	No of live and still births	No of cases of					
		Mongolism	Congenital heart disease	Hare lip cleft palate	Anencephaly	Spina bifida	Hydrocephaly
1944	4798	6	16	10	3	10	1
1945	4443	7	10	4	2	7	3

Mongolism

Incidence

84 mongols are known to have been conceived and born alive in the county during the twelve years 1944–55 2 mongols were stillborn Each case was confirmed by medical opinion Doubtful cases with "mongoloid" characteristics, and mongols who were conceived elsewhere but whose mothers moved into the county during pregnancy, were excluded from the survey No information was available in respect of mongols conceived in the county but born elsewhere

These data give an incidence of 1 mongol birth in every 613 live and still births (table I) Carter and MacCarthy (1951) found an incidence of 1 in 666 It will be seen from the table that more mongol births were recorded in the second six years of the period under review Though the incidence may have increased, it is probable that the records during the latter period are more complete and give a more accurate assessment, i e , 1 mongol birth for every 516 live and still births (In 1956 9 mongols are known to have been born, out of 4511 live and still births)

The incidence varied considerably from one year to another The lowest, in 1946, was 1 mongol birth for every 1160 live and still births , the highest, in 1953, was 1 in 362

The monthly distribution of mongol births was far from uniform Thus there is no record of a mongol birth during the eleven months beginning September, 1949, but 5 full-term mongols were born between June 8 and July 3, 1947—i e , more than 1% of the live births during this period

Grouping of Mongol Births

When the distribution of mongol births is considered in more detail it appears that about two thirds of them have occurred in small groups the remaining third were apparently isolated cases The following examples of groups are presented for illustration

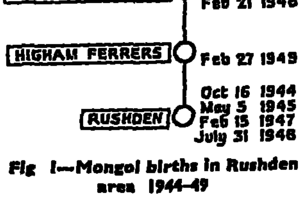

Fig 1—Mongol births in Rushden area 1944–49

Rushden Area

Rushden (population 15,210 in 1946), Higham Ferrers (population 3400), Irthlingborough (population 4700), and Finedon (population 3000) are linked by the road A6 In 1944–49, 10 mongols were born in this area (fig 1)

In the two years 1947–48 when there were 13 mongol births in the county, no fewer than 5 of these were in Rushden, Higham Ferrers, and Irthlingborough, whose populations and births are less than a tenth of those of the county. A mongol and an imbecile with some mongolian stigmata were born on the same day in Higham Ferrers and Irthlingborough, which are two miles apart

In Irthlingborough only 3 mongols are known to have been born in the twelve years but these 3 were born within a period of nine months 85 babies were born in Irthlingborough in 1947, so about 1 in every 21 babies born at this time was a mongol Also in 1945–47 there were born in this area 4 imbeciles for whose condition no cause could be found Their dates of birth were, in Rushden, Jan 27, 1945, and May 18, 1946, in Higham Ferrers, June 1 and June 8, 1947

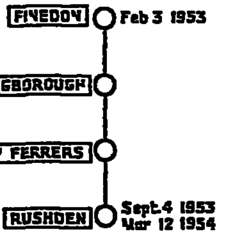

Fig 2—Mongol births in Rushden area, 1950–55

In 1950–55 only 3 mongol births were recorded in the same area, and all 3 births occurred within thirteen months (fig 2)

Oundle Area

In August, 1945, a mongol was born in Glapthorne (fig 3), where about 5 babies are born each year In December, 1946, a mongol was born in the hamlet of Stoke Doyle where about 2 babies are born annually On June 20, 1947, a full-term mongol was born at a farmhouse near Cotterstock. The next day another full-term mongol was born at Southwick Finally, a week later, a full-term mongol was born at Weldon In the nine years since then only 1 mongol has been born in this area

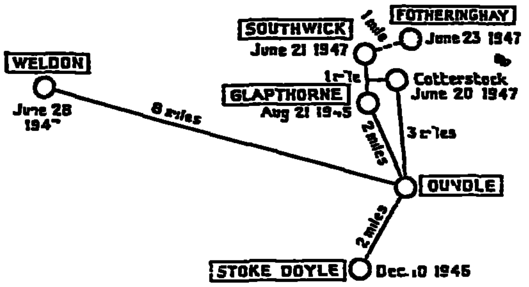

Fig 3—Mongol and imbecile births in Oundle area.

Only 2–3 babies are born each year in the neighbouring hamlets of Cotterstock and Southwick It seems a remarkable coincidence that, over a period of twelve years, 2 mongols were born on successive days in these two hamlets In Weldon, on a proportionate basis, 32 babies would have been born in 1947, and again it seems remarkable that the only mongol born in this village over the past twelve years was born a week after the 2 at Cotterstock and Southwick.

It is worth noting that on June 23, 1947, an imbecile, for whose condition no cause could be ascertained, was born at full term to a mother aged 26 about a mile from Southwick in the hamlet of Fotheringhay, where 3–4 babies are born each year

Wellingborough Area

9 mongols are known to have been born in the county in 1951 Of these, 5 were born in or near Wellingborough, 3 of them within seven weeks (fig 4)

On March 18 a mongol was stillborn at Wilby (population 523 in 1951 about 8 births a year) On May 20, a mongol was born at Holcot (population 350, about 5 births a year) On August 6 a mongol was born in Great Doddington (population 671, about 10 births a year) Three weeks later, a mongol was born at Little Harrowden, a village of about the same size A month later a 5th mongol was born in Wellingborough itself

Fig 4—Mo

Daventry Rural Di

5 of the 9 mong n described 2 other mo ural district about three mi weeks of each other

One birth was at Watfor , about 4 births a year), and the other in uses at Buckby Wharf, three miles away

An 8th mongol was born in Ke ring, and the 9th at Woodford

Corby Area

In the eight years 1944–51 there is no record of a mongol birth in this rapidly growing industrial town In 1952, however, 4 of the 6 mongol births recorded in the county took place in or near Corby (fig 5)

In February a mongol was born in Corby itself (population 18,050, with 449 births in 1952) Two months later a mongol was born in Great Oakley (population 272, with about 5 births a year) In November a full-term mongol was stillborn at Brigstock. Seven weeks later another full-term mongol was born in the same village (population 1098, with about 17 births a year) The only 2 mongol births recorded in Brigstock during the twelve years 1944–55 were within seven weeks of each other In July, 1953, a second mongol was born in Corby

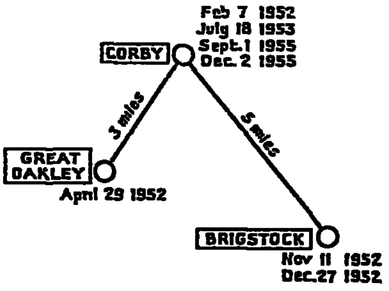

Fig 5—Mongol births in Corby area

In 1955 7 mongols are known to have been born in the county 2 were born in Corby within three months of each other

Urban and Rural Areas

The incidence of mongol births during the twelve years was not greater in towns than in the countryside, but the grouping is seen chiefly in the rural areas, where epidemiological patterns are always more distinct

Congenital Disease of the Heart

Incidence

From the sources already set out, the incidence of congenital heart-disease was assessed (table I) Of the 156 cases ascertained, 81 were obtained from the consultant pædiatricians, 5 from the school medical officers, and 70 from death certificates

The latter source is open to the criticism that, where necropsy was not performed, some cases of asphyxia livida and asphyxia pallida may have been diagnosed as congenital disease of the heart Nevertheless it is worth recording that the information thus obtained indicates the incidence of heart defect to vary from 1 per 243 live and still births in 1949, to 1 per 464 in 1946, the incidence over the twelve years under review being 1 per 338 live and still births (0 29%) This compares with an incidence of 0 24% in the obstetric units of University College Hospital and Queen Charlotte s Hospital, 1947–51 (Penrose 1955) failure to recognise early clinical evidence [illegible]ns of pregnancy and failure to give adequate exchange [illegible] the remaining 11

Attention is called to the fact [illegible]ere was no unusual con[illegible] hæmolytic disease of the new[illegible] areas As in mongolism, the large number of hospital[illegible]ion of the births suggests in some of cases seen is ver[illegible] for the staff [illegible] familiarit[illegible] It[illegible]

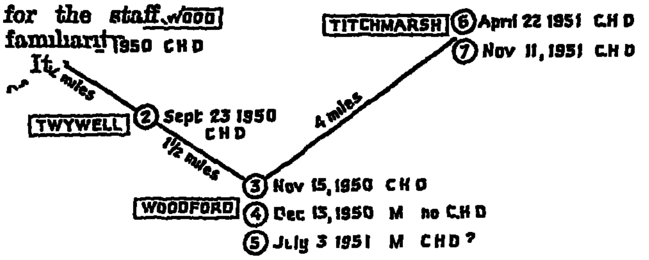

Fig 6—Births in Woodford area C H D = congenital heart-disease, M = mongol

places an infectious process Thus, of the 26 patients known to have been born in 1950–51, 5 were born in the Woodford area (fig 6) No others were born in these villages during the twelve years under review There was no known relationship between these cases

In 1951 (Census 1954) the populations (and annual births) were Grafton Underwood, 340 (about 5), Twywell, 339 (about 5), Woodford, 1435 (about 22), Titchmarsh, 538 (about 8)

Association Between Mongolism and Congenital Heart-disease

The geographical distribution of births of babies with mongolism and of babies with congenital heart disease sometimes suggests a common ætiological factor, since on occasions both conditions arise in the same area at about the same time (figs 6 and 8) Moreover, the incidence of congenital disease of the heart is high in mongols, and the pedigree of one family suggests a hereditary predisposition to both abnormalities in the same family

Hare-lip and Cleft Palate

Incidence

With these abnormalities, the incidence can be assessed with perhaps greater accuracy, for the diagnosis is obvious In the present survey, the cases ascertained give an incidence of 1 in 635 live and still births (table I) which is comparable with previous assessments cited in the literature The highest incidence was in 1950 (1 in 340 live and still births), and the lowest in 1947 (1 in 2506) Thus it varied considerably from year to year There was no unusual concentration of cases in urban areas

Geographical Distribution of Births

In 73 out of 83 cases it was possible to ascertain that the mother had lived in the area from the time of conception throughout her pregnancy The distribution of the births at times suggests an infectious process (fig 7), though this tendency seems less than with the other abnormalities There was no known relationship between any of the families affected in the Woodford Halse and Brackley areas

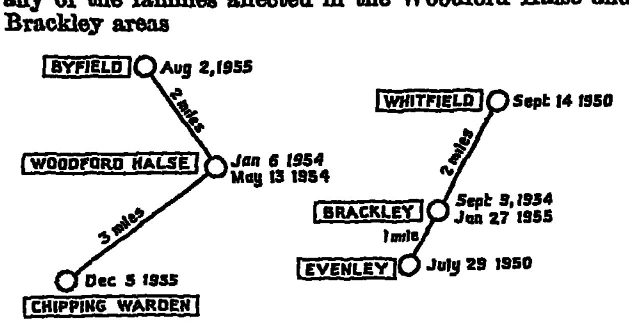

Fig 7—Births of children with hare-lip and cleft palate in two areas

In 1951 (Census 1954) the populations (and annual births) were Byfield, 796 (about 12), Woodford Halse, 1764 (about 27), Chipping Warden, 701 (about 11), Whitfield, 133 (about 2), Brackley, 2531 (about 38), Evenley, 382 (about 6)

No other cases of hare lip and cleft palate are known to have been conceived and born in these villages in 1944–55 In Brackley the years of births of infants with hare lip and cleft palate are the same as the years of births of mongols (figs 7 and 8)

Although this survey is restricted to 1944–55, it is worth recording that in Corby in 1955 and 1956, 8 babies were born with hare lip and cleft palate (i e, 1 per 170 live and still births), whereas in 1944–54 only 6 cases were ascertained (i e, 1 per 689) The months of birth in 1955 were May, July, and August, in 1956 4 of the 5 patients were born in the last six weeks of the year In November and December, 1956, 1 baby out of every 30 born in Corby had a hare-lip and cleft palate

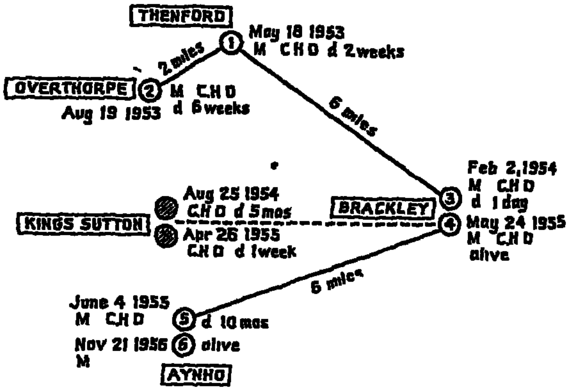

Fig 8—Births in Brackley area of infants with mongolism (M), congenital heart-disease (C H D), or both, showing age at death d = died.

Congenital Abnormalities of the Central Nervous System

Incidence

My figures for these abnormalities may well be incomplete since an analysis of all the causes of stillbirths could not be made It appears, however, that the geographical incidence varies considerably, and that anencephaly and spina bifida are subject to secular changes (Record and McKeown 1949) The incidence of central nervous system abnormalities (0 32%), compares with an incidence of 0 36% in University College Hospital and Queen Charlotte's Hospital, 1947–51 (Penrose 1955)

Geographical Distribution of Births

Only 46 anencephalic births were recorded, and it would be unwise to draw conclusions from so small a number Nevertheless it is worth reporting that the cases seem to be related to the density of population Thus the incidence in the urban areas is about double that in the rural areas, the incidence in the industrial belt is three times that in the rest of the county Most cases in rural areas arise not far distant from towns A similar distribution of hydrocephalic births is noted also, though the numbers are even more limited the urban incidence is nearly three times the rural incidence In contrast to the distribution of anencephalic and hydrocephalic births, there is no concentration in urban areas of babies born with spina bifida

When the anencephalic births are considered in more detail they are seen to occur in groups, as noted by P Del-Vesco as long ago as 1859 This grouping is less evident in cases of spina bifida and hydrocephalus, though in places the abnormalities seem to be associated

In 1954 there were 5 anencephalic births recorded in the county all of them were in Kettering—an incidence of about 1% of the live and still births in that borough

The dates of these births were April 16, May 16, Sept. 3, Sept. 5, Dec. 25. Of the other years in the period 1944–55, there were 2 anencephalic births in 1944, 2 in 1947, 1 in 1952, and none in any other year.

Loddington (population 315, with about 5 births a year). —The only congenital abnormalities recorded in this village over the past thirteen years are 2 cases of anencephaly. The infants were born in April and September, 1950; there was no known relationship between the families. (In 1950 6 cases of anencephaly were recorded in the county.)

Bozeat (population 1088, with about 17 births a year). —The only congenital abnormalities recorded are 1 case of spina bifida and 1 of anencephaly. Both were born at full term on the same day—Feb. 23, 1947. There is no known relationship between the families. (In 1947 6 cases of anencephaly and 10 of spina bifida were recorded in the county.)

Cransley (population 314, with 10 births in 1952 and 1953).—Only 2 cases of congenital abnormality are recorded in this village, but a mother who lived there until three weeks before her confinement gave birth to a baby with hare-lip and cleft palate. There is no known relationship between the families. The dates of birth were May 14, 1952 (anencephaly), June 29, 1952 (hare-lip and cleft palate), and Sept. 24, 1953 (anencephaly). Thus 3 of the 11 mothers living in Cransley during their pregnancies in 1952 and 1953 gave birth to abnormal babies. (In both 1952 and 1953 6 cases of anencephaly were recorded in the county.)

Wootton (population 1115, with about 18 births a year).—The only recorded cases of congenital abnormalities of the central nervous system in this parish are anencephaly on March 6, 1953 (this mother moved in at the seventh to eighth week of pregnancy); of spina bifida and hydrocephalus on Nov. 14, 1953; and of spina bifida and hydrocephalus on Feb. 3, 1954. (In 1953 6 cases of anencephaly and 5 of spina bifida were recorded in the county. In 1954 8 cases of spina bifida were recorded.)

Orthopædic Congenital Abnormalities

A complete survey was not undertaken of the incidence and distribution of talipes and congenital dislocation of the hip. The data obtained, however, in the present inquiry suggest an unusual distribution of births in these abnormalities also.

Association of Abnormal Births with Infections

The events recorded here could be due to chance; but on the face of it they suggest that some environmental factor induces congenital abnormalities—a factor which does not remain constant in any locality but is subject to variation. This environmental factor might be infection.

From a study of the epidemiological patterns of the notifiable infectious diseases in 1944–55, it seems that the distribution of mongol births has a closer association with scarlet fever than with any other infection. Most of the virus infections, however, are not notifiable, and the only epidemiological records relating to them are those provided in reports from head teachers of local-authority schools, who are asked to notify all such illnesses. These records are available only since 1951 and, though of very limited value, they too suggest that mongol births are more closely associated with scarlet fever than with other infectious diseases. In the first six year period both conditions were commoner in the north of the county than in the south, whereas in the second six years both were commoner in the south.

Seasonal Incidence

The seasonal incidence of births of babies with congenital heart disease has been described by Polani and Campbell (1954–55). McKeown and Record (1951) noted a seasonal variation of anencephalic births. My survey does not show any unusual seasonal distribution of conceptions or births of babies with hare lip and cleft palate. Classification of mongol births in individual months of the year is unsatisfactory since a considerable proportion are born prematurely; thus of the present series of 86 mongol births, judging by the information given by the mothers and by the records, 24 were premature, while 6 were overdue. From these data the *expected* dates of confinement were calculated and compared with the incidence of live births both in Northamptonshire and in England and Wales.

TABLE II—MONGOL DEVELOPMENT RELATED TO INCIDENCE OF SCARLET FEVER

—	Quarter			
	1st	2nd	3rd	4th
No. of mongol babies conceived (Northamptonshire, 1944–55)	22 (*26%*)	14 (*16%*)	23 (*27%*)	27 (*31%*)
No. of mongols 1 month after conception	22 (*26%*)	18 (*21%*)	16 (*19%*)	30 (*35%*)
No. of mongols 2 months after conception	31 (*36%*)	18 (*21%*)	14 (*16%*)	23 (*27%*)
No. of cases of scarlet fever (Northamptonshire, 1944–55)	384 (*28%*)	275 (*20%*)	271 (*19%*)	461 (*33%*)

Although the monthly figures of expected mongol confinements are small and subject to wide variation, it is noteworthy that the maximum incidence (approximately 40% of the total) was in the three months August, September, and October, when the national and county incidence of live and still births is steadily falling.

The ætiological factor responsible for mongolism is thought to operate within two months of conception. From the available data we can calculate the monthly and quarterly incidence of conceptions of mongol babies in Northamptonshire during the years under review. Unfortunately there is no information about the monthly incidence of notifiable diseases, but the figures for each quarter during the same period are known (returns to Registrar-General 1947–55). To compare the two sets of data, therefore, the conceptions were estimated on a quarterly basis. A comparison of the quarterly incidence of conceptions of mongols with that of notifiable infections shows a closer association with scarlet fever than with the other infections (table II).

Infant Mortality in Mongols

Of the 84 mongols born alive in 1944–55, 21 died in the first year of life—an infant-mortality rate of about 25%. It may be that the present survey is incomplete, particularly in the earlier years, in respect of mongols who died or moved out of the county in the first few months of life, and that the true incidence of mongol births and infant deaths is higher than the figures quoted. Nevertheless it is worth noting that in the first nine years of the survey (1944–52), 58 mongols were born, of whom 10 died in infancy including 1 in the neonatal period; whereas in the two years 1953 and 1954, 21 mongols were born, with 9 infant deaths including 4 neonatal deaths. In the last year, 1955, 2 of the 7 mongols born died in infancy.

If mongol births were not associated with an infectious process, one would expect an even distribution of such births in time and space and a progressive decrease in the number of infant deaths among mongols because of medical advances and economic improvement. If, however, mongol births were associated with an infectious process, one would expect variations in the incidence of the births, and fluctuations in the infant-mortality rate in relation to the severity of the infection. The incidence and distribution of mongol births and deaths in Northamptonshire support the hypothesis of infection.

The distribution of mongol deaths in the Brackley area deserves special mention (fig. 8). Of the 5 mongols born in this area in 1944–55, the 1st (born in May, 1953, in

Thenford) died after two weeks, from peripheral gangrene and coarctation of the aorta. The 2nd, born three months later only two miles away, died after six weeks from heart-failure due to congenital heart-disease. The 3rd, born in Brackley in February, 1954, died after one day and was found to have a patent interventricular septum. The 4th, born in May, 1955, in Brackley, was the only one to survive, and she is also thought to have a patent interventricular septum. The 5th, born two weeks after the 4th in Aynho, died after ten months from heart-failure due to a patent interventricular septum. The causes of death were verified at necropsy in all cases. It is also worth noting that 2 babies with congenital heart-disease who were not mongols were born in this area (at King's Sutton) in 1954–55. Both died, one after five months, the other after one week. In both cases the diagnosis was confirmed by autopsy.

In the present survey, records indicated that 14 out of 38 mongols appeared to have a heart defect—an incidence of more than 1 in 3. In the Brackley area however, all 5 mongols had cardiac defects—in 3 of such severity that they died in a few weeks; the 4th died within a year, and the 5th has a severe cardiac defect. (Clinical examination indicates that a mongol born in November, 1956, in this area has no heart defect.) It can be argued that such a concentration of gross heart defects in mongols in one area in a short period can occur by chance; but it is more easily explained by an infection, which was presumably of greater severity than elsewhere, since in no other part of the county is there a similar picture during the years under review. For example, no cardiac defect has been detected in the 6 mongols born in the Oundle area, 5 of whom are known to be alive (the sixth has moved out of the county).

Streptococcal Infections in Pregnancy

If mongolism is associated with a streptococcal infection in pregnancy, either one would expect a history of illness in the mother, or one must postulate that the mode of streptococcal infection is so selective that the fœtus is attacked without any maternal constitutional disturbance.

Attempts to associate a history of maternal illness in pregnancy with the subsequent birth of a mongol have not been convincing. In the present survey, of 35 mothers questioned, 12 gave a history suggestive of streptococcal infection in early pregnancy, but similar findings might well be obtained from a control group.

Lundstrom (1952) showed that the incidence of congenital heart disease was significantly higher in infants whose mothers had been exposed to rubella in the first four months of pregnancy, even when the mothers had previously suffered from rubella and gave no history of illness in pregnancy. Evidently, the fœtus is highly vulnerable during early pregnancy and can be attacked by an infectious organism when there is no sign of ill-health in the mother. There is reason to think that this may also happen with transplacental spread of streptococcal infections (De Lee 1916, Curtis 1916, Rosenow 1920, Nickel and Mussey 1927). The affinity of streptococcal toxin for rapidly dividing cells is well known.

Factors Known to be Related to Mongolism

Maternal age.—The fact that the incidence of mongolism is associated with maternal age does not exclude an infectious process. Acute rheumatism, and subacute bacterial endocarditis (Hobson and Juel-Jensen 1956), both of which are thought to be associated with streptococcal infections, have a higher incidence in certain age groups. A mother who is beginning or approaching the end of her childbearing period may be more subject to viral or bacterial attack than a young healthy woman. Moreover, dental sepsis is probably more common among mothers in the older age-groups.

Familial incidence.—The familial diathesis or predisposition of certain mothers to give birth to mongols or to babies with other abnormalities is compatible with an infectious process (cf. acute rheumatism). Turpin and Lejeune (1953) have reported the case of a girl who had acute rheumatism in adolescence and later gave birth to 5 mongols.

Social class.—The incidence of mongol births in the present survey appears to be higher among poorer persons. The incidence of infections is known to be higher among the poorer classes.

Discussion

Although it has been established that rubella plays an important part in the ætiology of congenital abnormalities, attempts to associate congenital abnormalities with other infections have been disappointing. The survey by Lundstrom (1952), however, indicated that the degree of immunity which will protect an expectant mother from overt illness is not necessarily sufficient to protect the fœtus. The epidemiological evidence in the present survey suggests that some abnormalities are the result of an infectious process; indeed sometimes its path can almost be traced in retrospect, through the community.

A survey of this kind can produce circumstantial evidence of the causal rôle of infections where clinical inquiry fails to elicit a history of illness or contact with illness. I cannot claim statistical significance for my data; but this is hardly surprising when one considers that not only can one infection, rubella, produce a number of different abnormalities, but also that one abnormality can probably be produced by a number of different factors. In addition, sex, heredity, and the critical time of attack are known to play their parts in determining the nature of the abnormality; their effects overlap the effects of infection, and the picture will often be confused and destroyed. Nevertheless it seems desirable that inquiries and surveys in other areas should be made.

It would be unwise on epidemiological evidence alone to try to establish which infection or infections are responsible for individual abnormalities. In the past attention has been concentrated on the virus infections, but there appears to be no reason to exclude bacterial agents. Congenital toxoplasmosis and congenital syphilis indicate that the placenta is no barrier to organisms; and some of them may act on the fœtus through exotoxins rather than by direct bacterial attack. The selective and toxic action of certain strains of streptococci on the fœtus, and the rôle of these bacteria in producing congenital abnormalities, may be greater than has been supposed.

The importance of establishing the association between infections and congenital abnormalities lies in the possibility of prevention. At present public health measures can be taken to try to prevent expectant mothers from coming into contact with rubella. Moreover, mothers who are exposed to rubella in early pregnancy can be partially protected with gamma globulin. If the Northamptonshire findings were corroborated, these preventive measures might have to be extended to expectant mothers exposed to other infections, to mothers in the vulnerable age groups, and to mothers who seem to have a hereditary predisposition to congenital abnormalities. Immunisation or chemotherapy as soon as pregnancy is diagnosed might tide both mother and fœtus over the early months of gestation. Perhaps in the future the protection of the individual against infection will start before or soon after conception rather than shortly after birth.

Summary

A survey has been made in Northamptonshire to ascertain the incidence and distribution of births of mongols and babies with certain other congenital abnormalities during the twelve years 1944–55.

Many of these births were geographically aggregated in a way that suggests that they resulted from infection

The known facts relating to mongolism and some other congenital abnormalities are compatible with an infectious ætiological factor In the present survey the seasonal incidence of mongol births, the severity of defect, and the distribution of deaths of mongol infants suggest that this abnormality is associated with infection of the mother—possibly streptococcal

If the Northamptonshire findings are corroborated, the public-health measures which are now undertaken to try to prevent fœtal abnormalities resulting from rubella infections might usefully be extended to protect the mother and fœtus from other infections

I should like to express my thanks to Dr C M Smith, county medical officer of health, Northamptonshire, for his encouragement in undertaking this survey to Prof L S Penrose for his advice, and to the consultant pædiatricians, surgeons, and obstetricians who let me see their records It also gives me pleasure to express my debt to the doctors who provided me with information in many cases, to the health visitors and district-nurse midwives for their conscientious inquiries on my behalf, and to the staff of the health department and the hospitals for the help they gave me

TRICUSPID STENOSIS

J F PANTRIDGE
M C, M D Belf, M R C P
PHYSICIAN

R J MARSHALL
M.D Belf, M.R C P.
PRINCIPAL REGISTRAR

ROYAL VICTORIA HOSPITAL, BELFAST

TRICUSPID stenosis is not infrequently found at necropsy in cases of rheumatic heart disease (Cooke and White 1941) It is almost always associated with mitral stenosis and often also with aortic valve lesions The presence of mitral stenosis tends to mask some of the signs and symptoms of the tricuspid valve lesions, and the diagnosis may thus be overlooked Bailey and Bolton (1956) explored the tricuspid valve at mitral valvotomy in 98 patients and found significant stenosis in 15, in only 3 of these had the diagnosis been established before operation

Until lately the diagnosis of tricuspid stenosis was of only academic interest Since 1953, however, occasional reports of tricuspid valvotomy have been published Hollman (1956) found details of 18 published cases and added another More recently 4 cases have been reported by Yu et al (1956) and 3 by Doglıotti et al (1956) It is clear that in suitably selected cases the operation is rewarding Tight tricuspid stenosis is extremely disabling, and we must hope that increasing awareness of its existence and its importance will lead to more cases being submitted for surgical correction

Of 400 patients selected for mitral valvotomy in the Royal Victoria Hospital, Belfast, 2 have also had tricuspid valvotomy, a 3rd patient has moderately severe tricuspid stenosis, but operation is not yet indicated In this paper we report these 3 cases and discuss the clinical, hæmodynamic, and surgical aspects of the condition

Case-reports

FIRST CASE

A girl, aged 19, was first seen in October, 1953, complaining of moderate dyspnœa on exertion and palpitation for the previous year She had no orthopnœa or hæmoptysis The jugular venous pressure was raised and there were prominent *a* waves The first sound in the mitral area was slapping in quality, a rumbling diastolic murmur with presystolic accentuation was maximal in the fourth left intercostal space just to the left of the sternum, and there was a blowing early diastolic murmur at Erb's point No murmurs were audible in the aortic area Fluoroscopy showed slight enlargement of the right atrium, there was no increase in pulmonary vascular markings Electrocardiography showed peaked P waves 2–4 mm high in the standard and precordial leads The diagnosis was mitral and tricuspid stenosis

Investigations

Cardiac catheterisation on Nov 17, 1954, showed the following pressures

Site	*Mean pressure (mm Hg)*
Right " pulmonary capillary "	1
Main pulmonary artery (rest)	5
Main pulmonary artery (exercise)	9
Right atrium	$4^1/_2$

The mean pressure in the right atrium equalled that in the pulmonary artery, in the absence of pulmonary stenosis this could be explained only by gross obstruction at the tricuspid valve

A year later (October, 1955) her condition had further deteriorated, she had dyspnœa and anginal pain after walking for a few yards and had frequent palpitation but no orthopnœa or hæmoptysis She felt weak and tired, and menstrual function had ceased The physical signs were unchanged Fluoroscopy showed considerable enlargement of the right atrium, the electrocardiogram (fig 1) was unchanged Femoral arterial blood was slightly desaturated (92%), and the hæmoglobin was 17 5 g per 100 ml

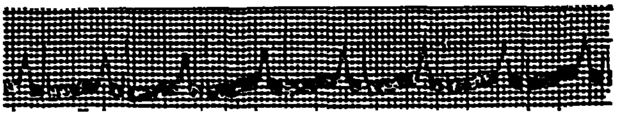

Fig 1—Electrocardiogram (case 1) showing tall peaked P waves in lead II

At cardiac catheterisation the right atrium was found to be grossly enlarged, the catheter repeatedly coiled up, and great difficulty was experienced in passing it through the tricuspid valve Pressures taken with a capacitance manometer and recorded on an Elmqvist four channel recorder (fig 2) provided conclusive evidence of tight tricuspid stenosis, right atrium 17/8 mm Hg (mean 10 mm Hg), right ventricle 15/0 mm Hg (mean 5 mm Hg)

Tricuspid Valvotomy

Mr T B Smiley operated on Feb 7, 1956, using a transverse sternum splitting approach The left atrium was entered through its auricle, and the mitral valve was found to be tightly stenosed, just admitting a finger tip A satisfactory valvotomy was achieved with the knife The right atrium was seen to be enormously enlarged and it too was entered through its auricle An extreme degree of tricuspid stenosis was found, the orifice was only a few millimetres in diameter A very satisfactory split was obtained with the finger No incompetence was noted at either valve before or after operation.

Progress

On return to the ward the patient was deeply cyanosed and cold, her peripheral pulses were impalpable, her blood-pressure was unrecordable, and her respirations were rapid and shallow Her pulse was irregular, with periods of asystole lasting up

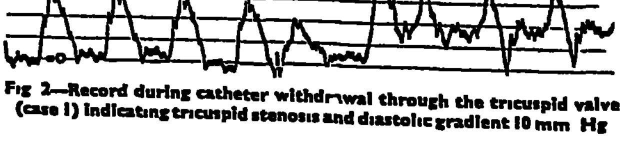

Fig 2—Record during catheter withdrawal through the tricuspid valve (case 1) indicating tricuspid stenosis and diastolic gradient 10 mm Hg

to five seconds Attempts to restore the blood-pressure by intravenous infusion of blood and of *l* noradrenaline were unsuccessful

Two days later she remained drowsy and cyanosed, with respirations rapid and shallow, pulse rapid though regular, blood pressure still unobtainable Triple rhythm was present Further attempts to restore the blood-pressure with *l* noradrenaline and hydrocortisone failed On Feb 11, four days after operation, she became conscious for the first time, with respirations improved, and systolic blood-pressure 90 mm Hg There was slight icterus, and the blood-urea level was 136 mg per 100 ml During the next week she rapidly improved, although the jaundice temporarily deepened The serum-bilirubin reached a peak of 5 9 mg per 100 ml, but other liver-function tests gave normal results The patient was fully ambulant on Feb 18, and was discharged home six days later with no evidence of hepatic or renal damage

Seen again in July, 1956, she was fit for all housework, walked several miles daily, and wanted to resume factory work Her jugular venous pressure was normal The mitral diastolic murmur was faint and no murmur was audible in the tricuspid area, but there were systolic and diastolic aortic murmurs The blood-pressure was 115/80 mm Hg

SECOND CASE

A housewife, aged 35, had uneventful pregnancies in 1946 and 1949 In 1954 she first noted moderate dyspnœa on hills and stairs Two years later she again became pregnant, the exertional dyspnœa steadily increased, and she had attacks of paroxysmal dyspnœa and orthopnœa

When she was admitted on Aug 15, 1956, the cardiac rhythm was regular, the mitral first sound was accentuated, there was a mitral diastolic murmur, and an early diastolic murmur was audible at Erb's point The uterus corresponded in size to a 28 week pregnancy Fluoroscopy showed gross pulmonary congestion, considerable enlargement of the right ventricle and the left atrium, and moderate prominence of the pulmonary trunk Electrocardiography showed evidence of right ventricular hypertrophy

Mitral Valvotomy

She was treated for a fortnight with complete rest in bed, a strictly salt free diet and mersalyl Since little improvement resulted from these measures, mitral valvotomy was performed on Aug 31, by Mr J A W Bingham The lateral commissure was satisfactorily split, and convalescence was uneventful apart from the onset of atrial fibrillation, which was controlled with digitalis

Six weeks after operation the patient was readmitted to hospital and was delivered of a child which was premature but survived During the puerperium the jugular venous pressure was high, the liver edge was palpable 15 cm below the costal margin, and the liver exhibited expansile pulsation A diastolic murmur was heard in the mitral and tricuspid areas and a systolic murmur at the lower end of the sternum

Cardiac catheterisation showed the following pressures

Site	*Mean pressure (mm Hg)*
Right ' pulmonary capillary	20
Main pulmonary artery	24
Right ventricle	14
Right atrium	14

An end diastolic pressure gradient was demonstrated across the tricuspid valve indicating the presence of tricuspid stenosis, and in addition a rise in intra atrial pressure at the time of ventricular systole indicated tricuspid incompetence (fig 3)

Tricuspid Valvotomy

At operation (Mr Bingham) on Nov 19, access to the tricuspid valve was through the wall of the right atrium Moderate stenosis with some incompetence was found The valve was split with the finger so as to make the orifice two or three times as large The amount of incompetence was unaffected

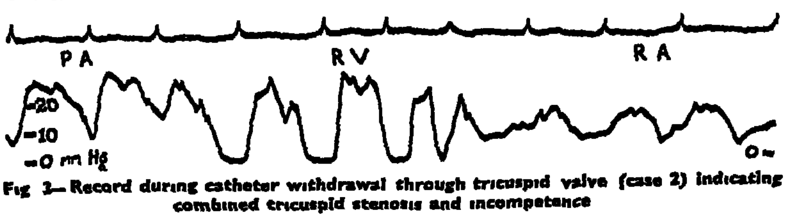

Fig 3—Record during catheter withdrawal through tricuspid valve (case 2) indicating combined tricuspid stenosis and incompetence

Convalescence was uneventful, and at the time of discharge the liver was smaller At review on May 15, 1957, improvement was maintained

THIRD CASE

A woman, aged 27, noted increasing dyspnœa on exertion since a pregnancy in 1949 When first seen in April, 1956, she was very breathless on hills and stairs and unfit for full housework

Her jugular venous pressure was slightly raised, and large *a* waves were seen A slapping first sound and a rumbling diastolic murmur in the mitral area were heard, and an opening snap was audible over the entire precordium The cardiac rhythm was regular Fluoroscopy showed slight increase in vascular markings, considerable enlargement of the right ventricle, and moderate enlargement of both atria Tall peaked P waves were present in the electrocardiogram, there was no evidence of right ventricular hypertrophy Cardiac catheterisation showed the following pressures

Site	*Pressure (mm Hg)*
Pulmonary " capillary " (resting)	(20)
Pulmonary " capillary " (after exercise)	(35)
Pulmonary artery	60/30 (40)
Right ventricle	60/0 (20)
Right atrium	10/5 (6)

(Mean pressures in parentheses)

The degree of pulmonary hypertension was consistent with severe mitral stenosis An end diastolic pressure gradient of 5 mm Hg across the tricuspid valve indicated tricuspid stenosis

Mitral Valvotomy

The mitral orifice was only a few millimetres in diameter A satisfactory split was achieved

Nine months after operation the jugular venous pressure was still raised and large *a* waves were seen A diastolic murmur in the mitral area was less conspicuous, but a diastolic murmur was easily audible over the lower end of the sternum, the opening snap was maximal in intensity in the tricuspid area Repeat cardiac catheterisation showed that the right ventricular systolic pressure was normal and the right atrial pressure was unaltered from that recorded before mitral valvotomy

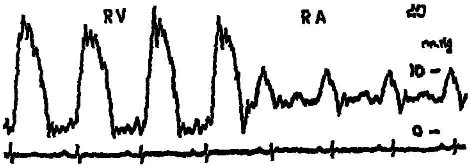

Fig 4—Withdrawal tracing (case 3) showing diastolic gradient of 5 mm Hg and large *a* waves on atrial tracing

Site	*Pressure (mm Hg)*
Right ventricle	17/0 (7)
Right atrium	10/5 (6)

(Mean pressures in parentheses)

Prominent *a* waves were still seen in the atrial pressure tracing, and the end diastolic pressure gradient was unaltered at 5 mm Hg (fig 4)

In view of the absence of symptoms tricuspid valvotomy has been postponed, it may well be required in the near future

Discussion

Symptoms and Signs

Thompson and Levine (1937) have pointed out that tricuspid stenosis resembles constrictive pericarditis in that cardiac filling is seriously impaired There is consequently a raised venous pressure and diminution of cardiac output, the latter causing fatigue and effort intolerance When, as in case 1, the tricuspid stenosis is critically tight, symptoms from the associated mitral lesion—e g, orthopnœa and hæmoptysis—are mild or absent, since the lungs are protected against congestion by the low fixed output from the right ventricle Conversely, when the tricuspid lesion is only moderate (cases 2 and 3), symptoms due to the mitral-valve lesion dominate the clinical picture, and the presence of a significant tricuspid lesion may become obvious only after a successful mitral valvotomy (case 2) Thus in any case of combined mitral and tricuspid stenosis the presenting symptoms depend on the relative severity of the lesions

Tricuspid stenosis raises venous pressure and in cases with sinus rhythm large presystolic *a* waves appear in the jugular venous pulse, these are similar to the giant *a* waves of pulmonary stenosis and pulmonary hypertension and indicate right atrial hypertrophy Presystolic hepatic pulsation may be found and must be distinguished from the systolic hepatic pulsation of predominant tricuspid incompetence In advanced cases the liver may be the seat of cardiac cirrhosis and a bronzed coloration of the head and neck (Altschule and Budnitz 1940) or frank icterus may be noted Characteristically, a rumbling diastolic murmur is heard at the left border of the sternum, but there may be difficulty in distinguishing it from the concomitant mitral diastolic murmur, it is said to be accentuated during inspiration and by turning the patient to the right (Chesterman and Whitaker 1955) The opening snap of the tricuspid valve may be heard (Kossmann 1955) According to Wood (1950) the most striking feature of tricuspid disease is that there may be gross physical signs suggesting right ventricular failure in patients who are practically free from symptoms A successful combined mitral and tricuspid valvotomy may unmask an aortic valvular lesion In case 1 no murmur was audible before operation in the aortic area, although a faint early diastolic murmur was audible at Erb's point After operation systolic and diastolic murmurs were heard in the aortic area although there was no alteration in the pulse pressure The postoperative appearance of these murmurs was clearly due to improvement in the hæmodynamic state, and in particular to augmentation of the left ventricular stroke volume

When tricuspid stenosis is suspected on clinical examination, confirmatory evidence may be obtained from fluoroscopy, electrocardiography, and cardiac catheterisation Fluoroscopy reveals enlargement of the right atrium Enlargement of the left atrium and of the right ventricle is due to the associated mitral lesion, and when the tricuspid stenosis is extreme (case 1) these changes may be disproportionately slight for the degree of mitral obstruction present In patients with sinus rhythm the electrocardiogram shows the peaked P waves of right atrial enlargement (fig 1), evidence of right ventricular hypertrophy is slight or absent

Cardiac Catheterisation

That protection from the hæmodynamic disturbances of mitral stenosis results from concomitant tight tricuspid stenosis is shown by the catheter findings in case 1 Although the mitral stenosis was undoubtedly severe at the initial examination in 1954, the pulmonary vascular pressures were subnormal (pulmonary "capillary" 1 mm Hg, pulmonary artery at rest 5 mm Hg, pulmonary artery during exercise 9 mm Hg) On the second occasion, when there was tight mitral stenosis, the catheter could not be manœuvred into the pulmonary artery, because it was impeded by the tricuspid stenosis however, the right ventricular systolic pressure was only 15 mm Hg (fig 2), and the mean pulmonary artery pressure could therefore not have exceeded 10–12 mm Hg

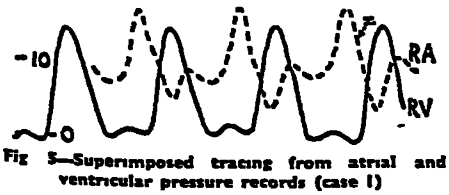

Fig 5—Superimposed tracing from atrial and ventricular pressure records (case 1)

Hæmodynamic changes on both sides of the tricuspid valve can best be studied according to the method of Ferrer et al (1953) by redrawing and superimposing pressure tracings from the atrium and ventricle (fig 5) This method is valid, since in case 1, the cardiac cycle was of constant duration (1 22 sec) in each tracing and there was very little respiratory fluctuation

In the normal heart the right atrial pressure equals the right ventricular end-diastolic pressure However, in case 1 the mean right atrial pressure is 10 mm Hg higher than the ventricular end-diastolic pressure and 5 mm Hg higher than the ventricular mean pressure The composite diagram shows that throughout ventricular diastole there is a constant atrioventricular pressure-gradient of not less than 8 mm Hg At the end of ventricular diastole, when the pressure is 0 mm Hg the corresponding right atrial pressure (Z point) is 12 mm Hg There is delay in the closure of the tricuspid valve with corresponding lengthening of the period of isometric contraction of the right ventricle The giant *a* wave 17 mm in height is caused by powerful contraction of the hypertrophied right atrium There is a rapid transient fall in intra-atrial pressure at the end of atrial systole, this is regarded by Yu et al (1956) among others, as an exaggeration of the X descent following vigorous systole in a distended right atrium No fall occurs in intra-atrial pressure at the opening of the tricuspid valve This provides confirmatory evidence of extreme tricuspid stenosis which prevents sudden discharge of blood into the right ventricle in early diastole

The pressure changes during the cardiac cycle in case 3 are similar but less (fig 4) The *a* wave measured 10 mm Hg and the pressure during atrial diastole is 5 mm Hg Since the ventricular end-diastolic pressure is 0 mm Hg, there is a 5 mm Hg pressure gradient across the valve The absence of any rise in intra-atrial pressure during ventricular systole indicates that there is no significant tricuspid incompetence

In case 2 successive cardiac cycles vary in length, and it is therefore impossible to superimpose tracings from atrium and ventricle The right ventricular pressure (fig 3) is 27/0 mm. Hg (mean 14 mm Hg) Since the atrium is fibrillating, there is no *a* wave However, there is a sustained rise in intra atrial pressure coinciding with ventricular systole, which indicates significant incompetence This is followed by a sudden drop in pressure to 5 mm Hg, corresponding to the opening of the tricuspid valve, and then a gradual rise until the end-diastolic pressure of 8–10 mm Hg is attained The record thus demonstrates combined stenosis and incompetence

Tricuspid Valvotomy

Hollman (1956) points out that incompetence complicates tricuspid stenosis more commonly than mitral stenosis, incompetence was absent in only 2 of the 9 published cases including his own for which information on this point was available Further, the danger of producing incompetence at operation is probably greater than in the case of the mitral valve Bailey (1955) and Chesterman and Whitaker (1955) advise that the anteroseptal commissure should not be divided because it renders the valve mechanically inefficient and may lead to incompetence It may therefore be advisable not to attempt complete relief of the stenosis, an orifice of 4 sq cm or more is probably adequate (Yu et al 1956) Instrumental splitting of the tricuspid valve is usually necessary since it is more leathery in texture than the mitral valve and is rarely calcified

The history of case 1, in which the manifestations of severe mitral stenosis were obscured by tight tricuspid stenosis indicates that mitral obstruction should always be sought and dealt with before tricuspid valvotomy When this is done the chances of pulmonary congestion and œdema due to loss of the 'protective' effect of the tricuspid stenosis will be avoided

The postoperative course of case 1 was complicated by extreme hypotension and hepatorenal failure The cause of the hypotension remains obscure , there had been no technical difficulty, excessive loss of blood, or hypotension during the operation There was no hæmoglobinuria or other evidence of incompatible blood-transfusion The long-continued postoperative hypotension was refractory to blood-transfusion and to intravenous infusion of *l* noradrenaline and hydrocortisone After recovery from the hypotensive state, hepatic and renal function rapidly returned to normal It might be postulated that, because of the preoperative hepatic congestion, unusual hepatic anoxia developed at operation or in the immediate post operative period with resultant excessive production of vasodepressor material

Summary

Tricuspid stenosis is a not infrequent complication of mitral stenosis The clinical features of combined stenosis of the mitral and tricuspid valves depend on the relative severity of the lesions

Three cases of tricuspid stenosis are reported In one the condition became apparent after successful mitral valvotomy In another, tight tricuspid stenosis completely obscured the changes in the lesser circulation expected from the presence of tight mitral stenosis

The clinical and hæmodynamic features of stenosis of the tricuspid valve are discussed

An unusual hypotensive state following combined mitral and tricuspid valvotomy is reported

OBSTRUCTION to the flow of urine has often been studied in experimental animals, but little is known about its effects on renal function in man The increasing incidence of prostatism in an ageing population provides a convenient opportunity to study this subject, and the development of reliable single-injection methods for the measurement of glomerular filtration-rate (G F R), renal plasma-flow (R P F), and maximal tubular excretory capacity (Tm) has simplified the technical problems involved (Robson et al 1949a and b, Ferguson et al 1950, Olbrich et al 1950a)

Using these methods, Olbrich et al (1950b) studied the effect of age on renal function, and showed that with advancing years G F R , R P F , and Tm were all decreased

We record here some observations of renal function in elderly patients with prostatism in an attempt to assess the effect on the kidney of obstruction to the flow of urine In addition to obstruction a further factor—infection—has had to be taken into account in many of the patients In a few observations have been made before and after prostatectomy

To exclude the effect of hypertension, which itself interferes with renal function in the elderly (Olbrich et al 1950b), we have confined our attention to patients with normal blood-pressures.

Methods

60 men with chronic urinary obstruction due to prostatic enlargement were investigated The average age was 72 (range 58–86) The main symptoms were frequency and difficulty in micturition, and all patients had some prostatic enlargement This was due to benign hyperplasia in 51 and to carcinoma in 9 The diagnosis was confirmed at operation in 34, at cystoscopy in 31, and at necropsy in 3

Three renal functions were studied (1) glomerular filtration-rate, which was measured by the method of inulin clearance (C_{in}) , (2) renal plasma flow, which was estimated by the method of diodone clearance at low concentrations (C_d) , and (3) maximal tubular excretory capacity, which was estimated by the use of diodone in high plasma concentration (Tm_d)

The methods, analytical technique, formulæ, and calculations have been described previously (Olbrich et al 1950c) The urine was collected by catheter to avoid inaccuracies caused by residual urine and incomplete emptying of the bladder All values were reduced to the standard of 1 73 sq m surface area

The renal-function tests were carried out in the early morning after an overnight fast No breakfast was allowed, but the patient was given about half a litre of weak tea before the test, followed by 150 ml of water every half to one hour during the investigation In this way hydration was achieved and the patients were able to maintain a good flow of urine, averaging 3–5 ml a minute

Routine observations in all cases included a bacteriological examination of the urine and a record of the body temperature, blood-pressure, and hæmoglobin, hæmatocrit, plasma protein, and blood-urea levels

Results

The G.F R was successfully estimated in all 60 patients The tests involving diodone, especially in high concentration, were in general well tolerated by the patients, but occasionally they led to considerable falls in blood pressure In spite of this reliable estimates of the R P F was achieved in 55 patients, and of Tm in 44

The urine was not infected in 32 patients and infected in 28 The average age of the uninfected group was 70 (58–81), and of the infected 74 (65–86) The range and average of the hæmoglobin, blood-pressure, plasma-proteins, and blood urea of the patients in these two groups are shown in table I

In normal elderly men G F R , R P F , and Tm were all reduced to about three quarters of the values in normal young adults (table II)

TABLE I—MEN WITH PROSTATIC ENLARGEMENT AVERAGE AND RANGE OF HÆMOGLOBIN, BLOOD-PRESSURE, PLASMA PROTEINS, AND BLOOD UREA

—	No	Hæmoglobin (g per 100 ml)	Blood pressure (mm Hg)	Plasma proteins (g per 100 ml)	Blood urea (mg per 100 ml)
Uninfected	32	11 3 (9 7–14 8)	153/84 (110/80–180/90)	6 9 (6 4–7 7)	50 (21–103)
Infected	28	10 5 (5 2–14 7)	152/87 (120/80–190/100)	6 7 (5 2–8 1)	47 (17–184)

TABLE II—RENAL FUNCTION IN MEN WITH PROSTATIC ENLARGEMENT WITH AND WITHOUT INFECTED URINE, COMPARED WITH NORMAL YOUNG AND AGED MEN

—	Age	G.F.R (ml per min.)				R.P.F (ml per min)				Tm_d (mg I per min.)			
		No	Mean	S D	% normal	No	Mean	S D	% normal	No	Mean	S.D	% normal
Normal young men *	20–39	9	126	16 7	100%	9	535	78	100%	8	41	7 4	100%

Men with prostatic enlargement (infected)	65–86	28	49	20 9	39%	23	219	82	41%	20	18	5 4	44%

* Figures from Olbrich et al (1950b)

In the uninfected prostatic group there was a striking contrast between the tubular function, which was well maintained at levels normal for the aged, and the G.F.R and R.P.F which were reduced to about two-thirds of the levels normal for the aged and to about half those of normal young adults

In the prostatic patients with infected urine, on the other hand, all three functions were diminished to about half of the normal for the aged and to about 40% of the normal for young adults

The differences for all three functions between the infected and the uninfected are statistically significant, especially that for tubular function, which exceeds the 0 1% level of significance

Derived Ratios

C_{in}/C_d—The G.F.R divided by the R.P.F is termed the filtration fraction and indicates the proportion of glomerular filtrate formed from each 100 ml of plasma flowing through the kidney This fraction remained relatively constant at about 25% in the normal subjects, whether young or old, as well as in the patients with prostatism (table III) The slight difference between the infected and the uninfected patients with prostatic enlargement was not statistically significant

C_d/Tm_d—The ratio between the R.P.F and the maximal tubular excretory-capacity for diodone gives a measure of the amount of plasma cleared of diodone per unit of functioning tubular tissue The ratio was slightly smaller in the prostatic patients, especially in the infected group, but none of the differences were statistically significant

C_{in}/Tm_d—The ratio between the G.F.R and the maximal tubular excretory-capacity for diodone gives a measure of the amount of glomerular filtrate per unit of functioning tubular tissue and provides an estimate of tubular efficiency in relation to glomerular activity The ratio was slightly less in the prostatic patients, especially the uninfected ones, but the difference was not statistically significant

Effect of Operation

12 of the patients who were submitted to prostatectomy were re-examined ten to ninety days after operation 10 were uninfected and 2 were infected

The G.F.R. increased in 6, decreased in 5, and was unchanged in 1 patient (table IV) The mean change was an increase of 13% (not statistically significant) The R.P.F, on the other hand, increased in every case save 1 by a highly significant average of 29%

As a result of the increase in R.P.F relative to the G.F.R, the filtration fraction fell after operation from a mean of 30% to 26%

Estimation of the Tm before and after operation was technically satisfactory in only 3 patients In these the excretion of diodone rose from an average of 29 (25, 43, 18) mg iodine per minute to an average of 36 (35, 52, 22) mg iodine per minute—an average increase of 28% (40%, 22%, 22%)

TABLE IV—EFFECT OF PROSTATECTOMY ON GLOMERULAR FILTRATION-RATE AND RENAL PLASMA-FLOW

Case	G.F.R. (ml per min)			R.P.F (ml per min)		
	Before	After *	Change %	Before	After *	Change %
1	126	126	= 0%	240	300	− 30%
2	30	60	−100%	157	274	− 75%

* Time 13–90 days after operation (mean 57 days) Cases 1–10 uninfected, 11 and 12 infected

Discussion

Our results show that in the elderly prostatic patient, chronic obstruction to the flow of urine leads to a reduction in R.P.F and G.F.R which is much greater than that caused by age alone. Tubular function, on the other hand, is unaffected unless the urinary tract becomes infected

These findings are contrary to those of Lich (1942), who has conducted the only previous comparable study of renal function in prostatism In a small series of 6

TABLE III—DERIVED RATIOS IN NORMAL YOUNG AND AGED MEN, AND IN AGED MEN WITH PROSTATIC ENLARGEMENT

—	Age	G.F.R./R.P.F (filtration fraction)			R.P.F /Tm_d			G.F.R /Tm_d		
		No	Mean	S D	No	Mean	S.D	No	Mean	S D
Normal young men *	20–39	9	23 8	2 8	8	13 3	2 4	8	3 2	0 7

* Figures from Olbrich et al (1950b) S.D = standard deviation.

patients he found that the glomerular function, as judged by inulin clearance, was only slightly reduced, whereas tubular function was much reduced but improved following surgical relief of the obstruction The reason for these differences may lie in the factor of infection, which Lich does not mention, or in the method by which tubular function was estimated, for he used phenol red and we used diodone The reduction of tubular function in the presence of infection is almost certainly due to pyelonephritis This is known to affect the function of the tubules more than any other part of the kidney (Bradley et al 1950, Bodansky and Bodansky 1952, Brod 1956)

In 12 patients, prostatectomy led to a decisive improvement in R P F but had no significant effect on the G F R The filtration fraction was accordingly reduced Successful estimations of tubular function before and after operation were achieved in only 3 of our patients, but in each there was a striking improvement (averaging 28%) This is in line with Lich's results

Our findings have some interesting affinities with experimental results of obstruction to the ureter Selkurt et al (1952) showed that a moderate increase in ureteral pressure to 52 cm of water caused a slight fall in R P F and G F R, but did not affect tubular function, a pattern similar to the findings in our uninfected patients Similarly, Share (1952) found that, in dogs, increasing the pressure in the ureter to 20–30 mm Hg caused a reduction in R P F and G F R The G F R was more affected than the R P F, with a consequent reduction in the filtration fraction In our patients both these functions were affected equally, and the filtration fraction was not significantly changed Unfortunately, Share made no observations on the function of the tubules

The mechanism by which R P F and G F R are reduced in prostatism is a matter for speculation It may be due to a nervous reflex relating urinary output to the pressure in the bladder, for it has been shown experimentally that distension of the bladder leads to a reduced output of urine, even after the ureters have been divided so as to exclude any hydrostatic connection between the bladder and the kidney (Tolls and Dille 1955) It may be due to a decrease in effective filtration-pressure within the lumen of the nephron, a view which looks back to the 19th century and the days of Ludwig and Heidenhain (Winton 1937), or it may be mediated by an effect on the venous system of the kidney An increase in pressure in the ureter is known to increase the intrarenal interstitial pressure (Gottschalk 1950), and this might be expected to compress the venules which lie within the substance of the kidney *It is also known that experimental obstruction of the venous outflow from the kidney leads to a decrease in renal blood flow and glomerular filtration, but has no effect on the function of the tubules (Winton 1931)* Changes of this kind were seen in our patients with chronic obstruction for as long as the urine remained uninfected, and the possibility is also supported by the effect of prostatectomy for an increase in the R P F was the principal postoperative change and there was no significant alteration in the G F R such as might have been expected from a simple fall in effective filtration-pressure

Whether any of these mechanisms in fact operate in the human kidney has not been definitely established and must remain a matter for future research Our findings show only that there is some general correspondence between the effects of experimental obstruction to the flow of urine in laboratory animals and the natural event in man They also go some way to suggest that compression of the renal venules by increased interstitial pressure may be the primary mechanism by which kidney function is diminished in prostatism

Summary

Single-injection methods with inulin and diodone were used to investigate the glomerular filtration-rate, renal plasma flow, and maximal tubular excretory-capacity in 60 elderly men with chronic urinary obstruction due to prostatic enlargement

The glomerular filtration-rate and renal plasma flow were reduced to about half the levels found in normal young adults and to about two-thirds of the levels found in healthy aged men Where the urine was infected these levels were reduced still further

In the absence of infection, tubular function was well maintained at levels normal for healthy aged men, but when the urinary tract became infected tubular function was affected to the same degree as the glomerular filtration-rate and the renal plasma-flow

In 12 patients examined before and after prostatectomy, there was a highly significant increase in the renal plasma flow after operation, but there was no significant change in the glomerular filtration-rate Tubular function was much improved in the only 3 patients for whom technically satisfactory estimations were obtained

These findings are discussed in relation to experimental urinary obstruction in animals Compression of the renal venules by increased interstitial pressure within the kidney with consequent obstruction to the renal plasma flow may be the primary mechanism

This study has been aided by grants from the Nuffield Foundation and from the scientific and research subcommittee of the Newcastle Regional Hospital Board

We are grateful for the cooperation of Mr J H Ross and Mr D A Sanford, who performed the operations, and to Mr D J. Newell for statistical advice

SOME MODIFICATIONS IN PLASTER-OF-PARIS TECHNIQUE

R S GARDEN
M B Aberd, M Ch Orth Lpool, F R C S E
CONSULTANT ORTHOPÆDIC SURGEON, ROYAL INFIRMARY, PRESTON

DURING the years of war, plaster of-paris played a significant part in the management of battle casualties, and lent itself readily to many of the modifications in treatment which were introduced The modifications described below were first developed during the Middle East campaign in response to some of the problems which beset the treatment of fractures at that time They constitute no major departure from normal routine, and were at first regarded as improvisations only In civilian practice, however, they have proved to be of more permanent worth, and publication is now undertaken in the hope that they may continue to be of occasional value

Application

Plaster of-paris casts are normally applied by unrolling wet individual bandages around body or limb, and there is probably no better way of securing a smooth, strong, and snugly fitting cast The method is time consuming, however, and there are occasions when this becomes of more than casual importance. At the end of a long operation the additional twenty minutes' anæsthesia while a thoracobrachial or a hip spica plaster is applied and allowed to set may indeed be vital. This was particularly true in field surgery, where it was imperative to avoid all factors likely to increase the degree of "shock." If, as has been shown, the mere transfer of a gravely wounded man from operating-table to stretcher may cause an immediate fall in blood-pressure, how much more disturbance must follow when such a patient is suddenly seated upright to facilitate the application of a shoulder spica? This upright position dare not be long maintained in a patient whose blood pressure is dangerously low following operation for a severe upper-limb injury, and, it may be, for a penetrating wound of the chest as well.

Of the various methods intended to hasten the application of this type of plaster cast, the "slab" technique is most widely used. In actual practice, however, this technique saves but little time and is difficult to manage single handed. Moreover it offends against the architectural preference for the strong tubular cast of uniform thickness as compared with one of unequal consistency. For the same reasons the "pattern" technique—so well described by Trueta (1944)—is not wholly satisfactory. Tailoring of the individual patterns is in itself a specialised task, and preparation of the patterns beforehand is seldom practicable if an accurate fit for every patient is to be obtained—and an accurate fit is essential in patients who may embark on a lengthy journey, without skilled supervision, within a few hours of injury.

The following technique has proved satisfactory in a considerable number of cases, and it is felt to be a safe and simple method of rapidly completing a plaster cast. By its means a shoulder or hip spica may be applied in a matter of minutes.

Three plaster bandages of the proprietary type are loosely rolled into one (fig. 1), and a stock of both 4-inch and 6-inch sizes is prepared and stored in airtight tins. When required, these composite bandages are well soaked in water and applied in the usual way. Care is taken to smooth each three-layer turn, as it is unrolled, to avoid "onion peeling," and each turn of the bandage is made to overlap the adjacent half of the preceding one. This produces a cast uniformly six layers thick, and any additional thickness which may be desired at points of stress is obtained by overlapping the turns at still closer intervals. In practice, this type of plaster dries rapidly, and cracking of the cast by inadvertent movement is minimised.

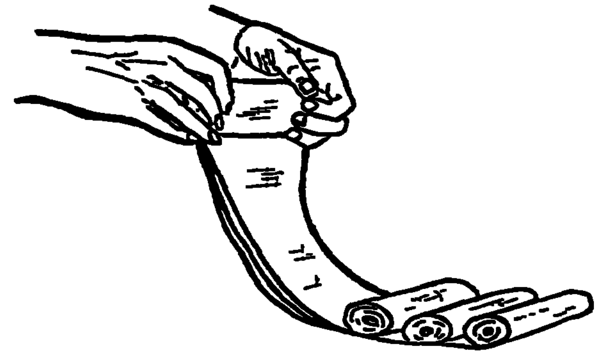

Fig. 1—Three-layer bandaging.

Although the urgency of the field surgical unit no longer obtains, these composite bandages may still be used for the larger types of plaster where speed of application is of advantage. The smoothness of the inner surface of the cast cannot, obviously, be so well controlled as when single bandages are used, and the use of composite bandages for skin-fitting plasters is therefore inadvisable. This need prove no real disadvantage, however, for it is clearly undesirable, in any event, to enclose a recently injured part of the body in a rigid and unyielding case.

Tibial Weight-bearing Plaster

This modification differs from the ordinary type of walking-plaster in so far as the body-weight is borne by the tibial tuberosities—much as in the case of a below-knee amputation—whilst the foot and ankle remain completely free. It was originally devised to relieve the tedium of prolonged recumbency in soldiers who had sustained bilateral fracture of the os calcis after a land-mine explosion and were being treated by non-weight-bearing exercises in bed. Since then it has proved equally effective in the treatment of other injuries of the foot and ankle where direct weight-bearing is contra-indicated.

The value of non-weight-bearing exercises is enhanced by this plaster, and the patient becomes ambulant without danger of direct weight-bearing on the fracture site. Active movements are encouraged as the patient walks, and, since a sock and soft shoe may be worn, the resulting gait often looks surprisingly normal.

Application of the plaster requires more than ordinary care.

A strip of thick adhesive felt, 3 inches wide, is first applied round the limb at the level of the tibial tuberosities, and a similar strip is placed in position just above the malleoli. The area which remains exposed between these two felt strips is protected by a layer of cotton-wool, and a light plaster is then applied. Half an inch of felt is left uncovered at either end, and the plaster is firmly moulded in the region of the tibial tuberosities and over the supramalleolar area. An ordinary Böhler walking-iron is then fixed in position, a clearance of at least 2 inches being left between the patient's heel and the bend of the iron (fig. 2).

In this way a cast is fashioned which is prevented from riding upwards by the cone-shaped tibial tuberosities and from slipping downwards by the flare of the malleoli. When the patient begins to walk, he soon discovers that dorsiflexion of the foot tightens the calf muscles and thus tends to fix the limb more firmly in the cast. Any tendency to foot-drop is thus corrected.

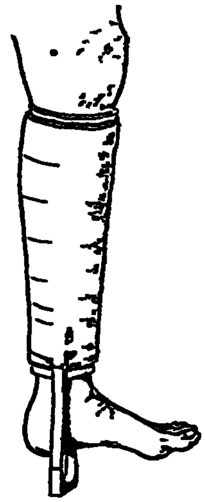

Fig. 2—Tibial weight-bearing plaster.

Some "pistoning" of the limb within the cast is inevitable, but this will be slight if the cast has been carefully moulded. Undue up-and-down movement will produce friction sores, but these may be largely prevented by the use of an aluminium walking-iron in conjunction with as light a cast as possible.

Swelling as a result of dependency has not proved troublesome when this plaster has been used, but gross swelling which has been present before its application has almost always been aggravated. Such swelling should be allowed to subside, therefore, before the plaster is applied. Too much walking is best discouraged at first, since the skin over the head of the tibia requires a little time in which to accustom itself to this unusual means of progression.

Wedging

The expedient of wedging a plaster cast to correct faulty alignment of a fracture has long been practised and is of accepted value. Where the adjustment required is small, wedging provides a means of correction without resort to removal and reapplication of the whole cast with, as often happens, failure to effect improvement in position. When wedging is done by guesswork, the same-

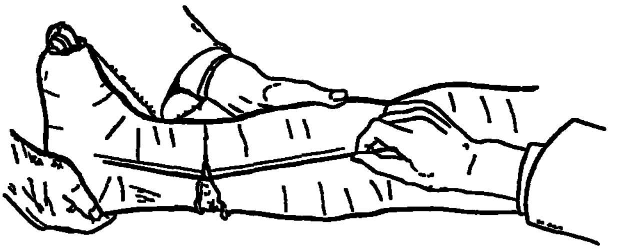

Fig. 3—Wedging.

failure to achieve correction at the first attempt is not unusual. Fluoroscopy provides an accurate means of control in gauging the amount of wedging required, but, apart from the image intensifier, its use is precluded by the danger which exists both to the patient and to the surgeon's hands.

Adjustment of alignment may be found possible at the first attempt in the following way:

A straight line is first pencilled on the appropriate surface of the plaster, and, by reference to the X-ray film, the site of fracture is carefully determined, and its position is marked on the cast. A Kirschner wire is then angulated to conform precisely with the deformity as shown on the X-ray film. The cast is divided transversely at the fracture site for at least half its circumference on the side opposite the angulation. Correction by manipulation is then made in the usual way. While this is being done, the Kirschner wire is held over the cast and manipulation is continued until the straight line previously drawn on the plaster angulates to correspond with the bend of the wire (fig. 3). Full correction should then have been obtained. The wedge is filled with cotton wool, and a plaster bandage is applied to restore the integrity of the cast.

Alternatively the angle of deformity may be drawn on the cast and correction continued until the angle is completely reduced.

When both lateral and anteroposterior angulation are present, the above procedure may be duplicated. It is preferable to cut the plaster transversely and to open the cut into a wedge, which increases the capacity of the cast, rather than to remove and then close a wedge, which reduces the capacity of the cast.

Gross faults in alignment are, of course, unsuitable for correction by wedging, and anæsthesia is best avoided. The manipulation need not be painful, and the conscious patient can give adequate warning if undue pressure is exerted.

Plaster-of-paris and the Thomas Splint

The combination of plaster-of-paris with the Thomas splint has already been well exemplified in the "Tobruk" plaster (Jack 1944), which did so much to ease the evacuation of severely wounded Service personnel. Complete comfort for these patients was not always possible, however, because the rings fitted to the Thomas splints were too big. In the field it was customary to fill the interval between the outer half of the ring and the patient's thigh with shell dressings, which were retained in position by the encircling plaster. When, however, the Thomas splint was used with fixed traction for the definitive treatment of the fractured femur, some more stable form of adjustment became necessary. The efficiency of the Thomas splint depends almost entirely on a well-fitting ring which allows counter-pressure to be maintained against the tuber ischii. Much has been done to discredit this splint by the use of unduly large rings which slip upwards to press in the groin and perineum almost as soon as they are applied. This gives rise to intense discomfort, and the patient's inability to tolerate such splintage can readily be understood.

In the case of the walking calliper, the problem of ring size was solved early in the war by the introduction of the Charnley adjustable splint (Charnley 1947)—an appliance still very much in active service. The same adaptability in the Thomas splint, however, was not at that time available, and as a substitute for a properly fitting ring the following manœuvre was then employed:

A strip of adhesive felt, about 8 × 3 in., is placed on the skin over the anterolateral aspect of the upper thigh, and the ring of the splint is then pulled forwards and outwards until it abuts comfortably against the tuber ischii. While the ring is maintained in this position, and before the extensions have been tightened, the interval between the felt and the ring is filled with wet unrolled plaster-of-paris bandages. These are moulded by lateral pressure until they conform to the outer aspect of the thigh and to the inner surface of the ring. A thin plaster slab is then applied over both ring and bandages to hold the latter in place (fig. 4).

In this way the splint is made to fit the particular limb to which it has been applied, and the patient's comfort is assured.

Subtrochanteric Fracture of Femur

In the management of fractures of the upper femoral shaft, where persistent abduction of the proximal fragment is so often troublesome, the use of a well-fitting ring is essential. Control of this abducted upper fragment is not easy to obtain without operation, but the lower fragment remains under control and can readily be abducted to bring it into line with the upper fragment.

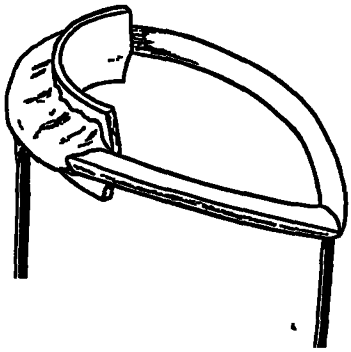

Fig. 4—Modification of Thomas splint.

A well-fitting ring which presses firmly against the tuber ischii and conforms to the contour of the thigh over the rest of its circumference cannot be made to tilt except by a corresponding tilt of the pelvis. If, therefore, the angle between the side-bars of the splint and the ring is decreased, the limb will be abducted accordingly. This alteration of angle can best be achieved by dividing the outer bar of the splint at the level of the fracture and bending the inner bar outwards until the required degree of abduction has been obtained. The splint is then reconstituted by the application of a plaster-of-paris bandage over the cut ends of the outer bar, where they overlap as a result of the altered angle (fig. 5). This procedure virtually amounts to wedging of the Thomas splint and is a less clumsy means of correcting alignment than by widely abducting both splint and limb beyond the edge of the bed. It has the additional advantage of allowing the patient to be transferred without disturbance of the fracture.

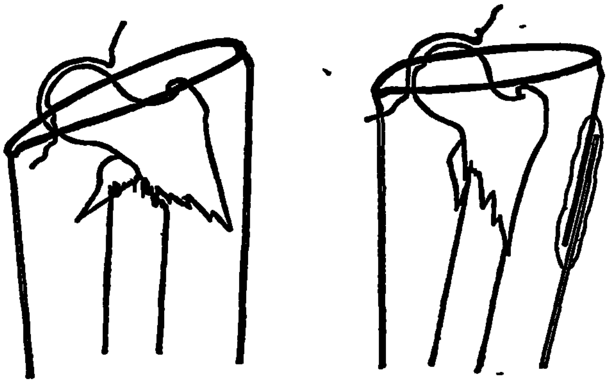

Fig. 5—Subtrochanteric fracture of femur.

Toe Protection

This simple expedient was introduced to counteract the ill effects of badly applied plaster-of-paris platforms which maintained the toes in forced dorsiflexion and thus led to stiffness and, on occasion, to permanent limitation of movement.

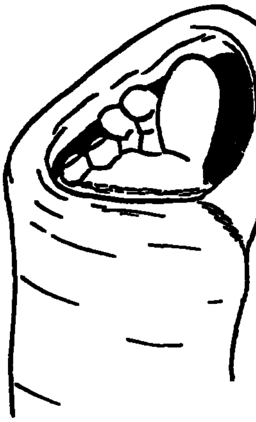

Fig 6—Toe protection

It consists of a loop of plaster (fig 6) which bridges the toes and protects them from the weight of bedclothes and accidental injury. Bed-cradles are seldom practicable when a patient is evacuated by ambulance, nor, in civilian practice, are they always available in the home. The weight of blankets can force the toes into plantar flexion and initiate deformity very easily. With this loop, the toes remain free, and flexion contracture or other deformity has not been noted as a result of its use. The plaster platform, never fully justified, is best reserved for sciatic or peroneal paralysis when active support is really required.

THE nail bed capillaries have been studied in hypertension by Boas and Mufson (1923) and Brown and Roth (1927). Recently emphasis has shifted to the investigation of conjunctival capillaries. In hypertension Lack et al (1949) described severe thinning of the conjunctival capillaries, and Lee and Holze (1951) published photographs of narrowed conjunctival capillaries.

We have examined the morphology of both conjunctival and nail bed capillaries and capillary pressure in the nail-bed in hypertensive and control patients. The relation of the capillary findings to the cardinal clinical features of hypertension was studied.

Material and Methods

100 outpatients with established diastolic hypertension were studied and followed up for periods varying from one to five years. Excluded from the study were patients in whom the fundus could not be seen because of cataract and corneal opacities. Also excluded from the present report were patients with high systolic pressure but normal diastolic pressure, patients with nephritis, and patients with hypertension complicating diabetes mellitus.

In all the patients attention was paid to presence of proteinuria, changes in the fundus, classified by the method of Keith et al (1939), and symptoms and signs and tests of cardiac and cerebral complications. All the patients with proteinuria underwent microscopy of the urine and relevant blood tests, and also radiography of the kidneys where clinically indicated.

Heart disease was termed severe in the presence of congestive cardiac failure or auricular fibrillation or severe coronary disease or if there was severe cardiac enlargement radiologically or if the electrocardiogram was decidedly pathological. There were 37 such patients.

The cerebral complications noted were gross intellectual deterioration with hypertensive encephalopathy in 2 patients and hemiparesis or hemiparalysis in 5 others.

The nail-bed capillaries were examined at magnifications of 50–150. The bulbar conjunctiva was examined with a slit-lamp at magnifications of 12, 24, and 48. In many patients the nail-bed and conjunctival capillaries were photographed. The diameter of the lumen of the capillaries was measured by using clear photographs incorporating an ocular scale in which the actual distance represented between divisions and the actual width represented by a line between the divisions had been measured.

Thus in the nail bed the width of a line in the ocular scale at 60 × was 4 5 μ, and the distance between the beginning of one line and the beginning of the next was 17 μ.

The corresponding figures for the conjunctiva at 24 × were 6 7 μ and 25 μ. Photographs were enlarged and the capillaries measured against line and division. In the nail bed the "arteriolar" limb of the capillary was measured.

With practice a close estimate of capillary width could be made at the time of examination in terms of width of line and space of ocular scales.

Capillaries were put in two groups according to diameter: one group included normal capillaries with a range of diameter 5–12 μ (fig 1) and moderately thin capillaries with a range of diameter 3 5–5 μ (fig 2), and the second group comprised very thin capillaries with diameters of 2–3 5 μ (fig 3).

Although the methods of measurement are subject to appreciable error, the inaccuracies were not such as to invalidate the range of values given. In view of the natural variation in width of the capillaries the classification was only applied to the conjunctiva and nail-bed as a whole if the findings were characteristic of most of the capillaries seen.

The capillary blood-pressure was taken by the method of Davis (1953), and with practice the method became a routine procedure.

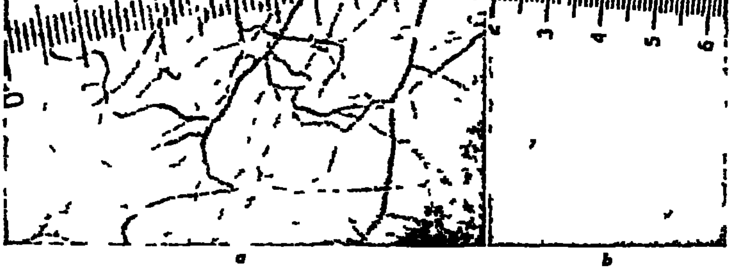

Fig 1—Normal capillaries: *a* conjunctival (smallest vessels in spaces framed by darker venules) (× 12); *b* nail bed (× 40).

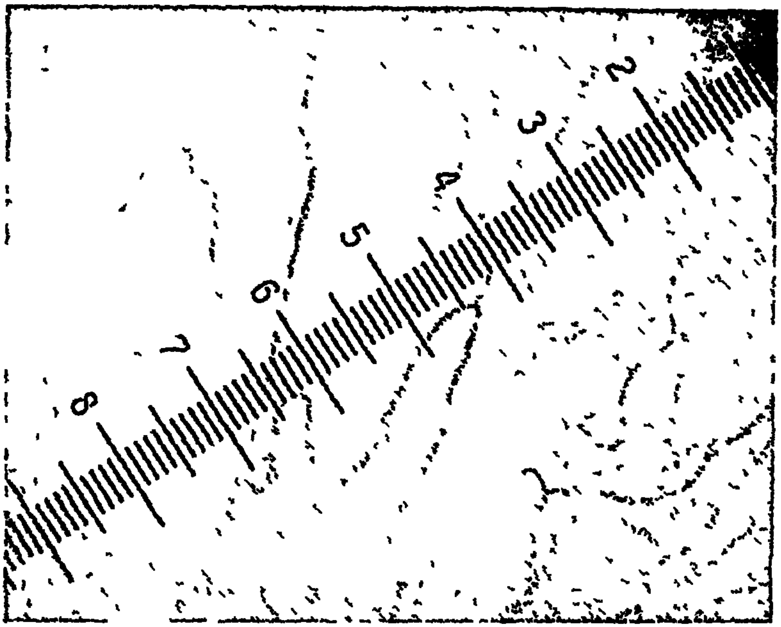

Fig 2—Moderate thinning of conjunctival capillaries in hypertension (× 54)

To estimate capillary pressure the principle of ordinary clinical sphygmomanometry was adapted for the nail bed A manometer cuff made for the newborn infant's arm was attached to an ordinary sphygmomanometer and fastened round the second phalanx and distal interphalangeal joint of the finger The nail bed capillaries were observed under the microscope The pressure in the cuff was quickly raised until all visible capillary blood flow stopped The pressure was then reduced until normal flow reappeared in several capillaries This pressure was taken as the capillary pressure

Capillary pressure less than 45 mm Hg was considered normal (45 cases), pressure 45 mm Hg or more was considered high (55 cases)

Of the 100 patients 28 were males and 72 females There were 65 patients aged less than 60, and 35 aged 60 or more

Results

The capillary blood pressure and the diameter of the lumen of the capillaries were not related to the sex or age of our patients The findings are set out in tables I–III, and the main statistical assessments in table IV

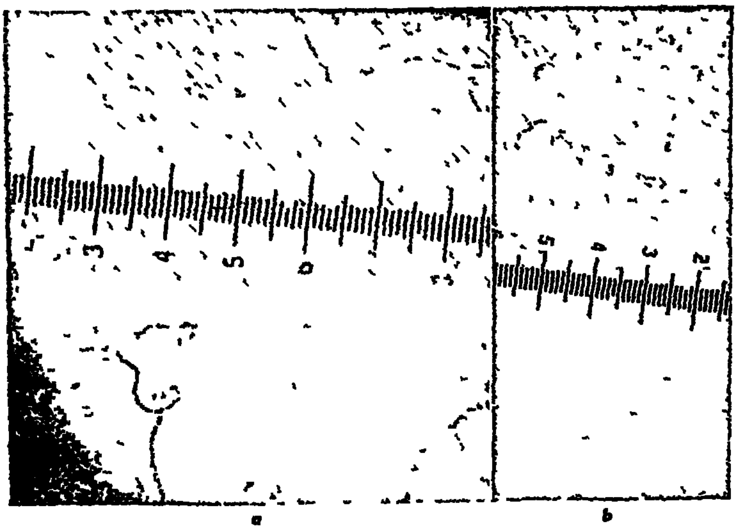

Fig 3—Severe hypertension *a* conjunctival capillaries are less than 3 μ in diameter and invisible in photograph, smaller visible vessels being venules and arterioles, also very thin (× 37) *b*, nail-bed capillaries are very thin (× 40)

Fundus (table II)

A normal fundus was not found where the conjunctival capillaries were very thin Grade 4 fundus was not found where the conjunctival capillaries were normal or moderately thin Of the 10 patients with grade 3 or grade-4 fundus 8 had very thin conjunctival capillaries Proteinuria was significantly associated with fundus grades 2, 3, and 4 (coefficient of association 0 58, χ^2++)

Capillary Thinning (table II)

This correlation between severe conjunctival capillary thinning and proteinuria was 0 45, which, though it just failed to be statistically significant, suggests a trend, and possibly in a larger series a significant correlation may be revealed

Severe conjunctival capillary thinning showed a trend of correlation with fundus changes and a positive correlation with high capillary pressure

Severe nail bed capillary thinning had a negative correlation with proteinuria and no correlation with fundus changes but was significantly correlated with severe heart disease (correlation 0 61, χ^2++), high capillary pressure, and severe conjunctival capillary thinning The nail-bed capillaries were very thin in only 16 of 48 patients with very thin conjunctival capillaries

TABLE I—RELATION OF FINDINGS IN HYPERTENSION TO PROTEINURIA

Finding	*No proteinuria or traces only (69 cases)*	Proteinuria (31 cases)
Diastolic pressure (mm Hg)		
Less than 120	50	18
120 or higher	19	13
Fundus		
Normal, stage 1	39	8
Stage 2 3, 4	30	23
Nail bed capillaries		
No or moderate thinning	52	26
Very thin	17	5
Conjunctival capillaries		
No or moderate thinning	41	11
Very thin	28	20
Capillary pressure		
Normal	38	7
High	31	24

However, when severe thinning in the nail bed was found it was mostly associated with severe thinning in the conjunctival capillaries

The lumen of the capillary was assessed in 100 control medical outpatients with conditions unconnected with hypertension Severe capillary thinning was seen in the conjuntiva in 3 and in the nail-bed in 8

Capillary Pressure (table III)

The correlation between high capillary pressure and high diastolic pressure of 120 mm Hg or more was 0 40, which although not statistically significant suggests a trend The incidence of fundus stage 2, 3, 4 was significantly increased in the presence of high capillary pressure As regards fundus 3 and 4, nine out of ten occurred in the presence of high capillary pressure

High capillary pressure was found in 55 of the 100 hypertensives In 69 patients with normal blood-pressure Davis (1953) found 8 with high capillary pressure

High capillary pressure had a significant correlation with proteinuria (0 62, χ^2++), changes in the fundus (stage 2, 3, 4), severe

TABLE II—CAPILLARY THINNING IN CONJUNCTIVA

—	None or moderate (52 cases)	Very thin (48 cases)
Diastolic pressure (mm. Hg)		
Less than 120	38	30
120 or higher	14	18
Fundus

Heart-disease		
None or moderate	37	26
Severe	15	22
Cerebral arteriopathy	1	6

thinning of nail-bed capillaries, severe thinning of conjunctival capillaries, and severe heart-disease. With the last named the correlation was 0·47, χ^2+.

Severe heart disease complicating hypertension was positively associated with high capillary pressure and severe thinning of nail-bed capillaries. The correlation with the latter was 0·61, χ^2++.

Of the 7 patients with cerebral arteriopathy 6 had severe capillary thinning and high capillary pressure. These figures are too small for statistical significance, but the trend is suggestive.

Discussion

In hypertension Lack et al. (1949) described extensive narrowing of the conjunctival capillaries with tubular thickening of walls and loss of normal distensibility. They claimed that 98% of hypertensives showed significant capillary changes. The severity of the pattern was correlated with the rise in diastolic pressures. Control patients showed minimal changes in 28%, but none showed the hypertensive pattern.

In the conjunctiva of hypertensive patients Lee and Holze (1951) found vasoconstriction of the minute arterioles and metarterioles. They described elongation, looping, and tortuosity of the true capillaries, including the smaller collecting venules.

A guide to the microscopic study of the conjunctiva in health and disease is found in the comprehensive study of Bloch (1956).

In hypertension, particularly with increasing proteinuria, Sieker et al. (1955) found a decreased retinal reactivity to raised oxygen tension in the blood. In the present study proteinuria was significantly associated with high capillary pressure and pathological changes in the fundus and possibly with severe conjunctival capillary thinning. There was correlation between high capillary pressure in the nail-bed and severe thinning of the conjunctival and nail-bed capillaries. Although conjunctival capillaries were more often very thin than were nail-bed capillaries, there was correlation between severe conjunctival capillary thinning and severe nail-bed capillary thinning. Morphologically the conjunctival capillaries are those of a network in a membrane, whereas those of the nail-bed are individual loops seen in their whole length. In rheumatic fever Davis and Landau (1956) have shown that the conjunctival capillaries were a more sensitive index of systemic pathology than those in the nail-bed. Yet high capillary pressure in the nail-bed is closely related to both conjunctival and nail bed severe capillary thinning and to the complications of hypertension.

TABLE III—CAPILLARY PRESSURE

Heart-disease		
None or moderate	34	29
Severe	11	26
Cerebral arteriopathy	1	6

The method of measuring capillary pressure described by Davis (1953) has proved useful in this study. Perhaps this method really measures the arteriolar pressure, but the values so obtained in healthy controls were the same as those found by Landis (1930) using the direct method of a microcannula in the capillary. However, since in some of the present patients the capillary pressure was nearly as high as the diastolic pressure, it is possible that precapillary arteriolar pressure was really being measured. Alternatively in certain circumstances the capillary resistance may be so increased as to bring the capillary pressure close to arteriolar pressure. Boas and Mufson (1923), studying capillary pressure in the nail-bed, mentioned this possibility. Our finding that with high capillary pressure the conjunctival capillaries were nearly always very thin may support this view.

TABLE IV—COEFFICIENT OF ASSOCIATION *

—	Diastolic pressure 120 mm. Hg or higher	Fundus 2, 3, 4	Nail bed capillaries <3·5 μ	Conjunctival capillaries <3·5 μ	High capillary pressure

* By Margaret P. Yekutiel.

Of the 7 patients with cerebral arteriopathy 6 had severe capillary thinning and high capillary pressure. Byrom (1954) investigated in rats the pathogenesis of hypertensive encephalopathy. His fig. 14 illustrating diffuse and focal spasm in the smaller arteries, with intense thinning of the terminal arteries, in severe hypertension resembles our findings in the precapillaries and capillaries in severely hypertensive patients.

The evidence submitted here shows that the capillaries are altered in hypertension. High capillary pressure measured in the nail bed is significantly associated with some of the chief complications of hypertension—proteinuria, fundus stage 2, 3, and 4, and severe heart disease—and possibly with cerebral arteriopathy. High capillary pressure is not closely associated with diastolic pressure of 120 mm. Hg or more, although there is evidence of such a trend. Perhaps, once the diastolic pressure has reached 95 mm. Hg and remains persistently high, a further rise in diastolic pressure is not the main factor influencing capillary pressure. High capillary pressure is closely associated with severe capillary thinning. There is evidence, although in the main not statistically significant, that severe conjunctival capillary thinning may be associated with the same complications of hypertension as high capillary pressure.

This study shows the importance of investigating both conjunctival and nail-bed capillaries

Summary

In 100 patients with hypertension and in control patients the capillaries of the nail-bed and conjunctiva were examined by capillary microscopy and with slit-lamp and often photographed

The diameter of the lumen of the capillaries was measured, and the blood pressure in the nail bed capillaries was taken

The range of diameter of normal capillaries was 5 0–12 0 μ, of moderately thin capillaries 3 5–5 0 μ, and of very thin capillaries 2 0–3 5 μ

Very thin nail-bed capillaries were found in 22 and very thin conjunctival capillaries in 48 of the 100 hypertensives In 100 control patients without hypertension very thin capillaries were found in the nail-bed in 3 patients and in the conjunctiva in 3 patients

Capillary blood-pressure less than 45 mm Hg was considered normal Capillary pressure 45 mm Hg or higher was considered high and was found in 55 hypertensives High capillary pressure was not closely correlated with diastolic pressure of 120 mm Hg or higher

High capillary pressure had a significant correlation with proteinuria, changes in the fundus (stages 2, 3, 4), severe nail-bed and conjunctival capillary thinning, and severe heart-disease There was a trend of association with cerebral arteriopathy In 69 patients with normal blood-pressure high capillary pressure was found in 8

Severe conjunctival capillary thinning had a trend of association with proteinuria, changes in the fundus, and cerebral arteriopathy

Severe nail-bed capillary thinning was significantly correlated with severe conjunctival capillary thinning and severe heart disease

Severe capillary thinning was significantly correlated with high capillary pressure

The combined study of both conjunctival and nail-bed capillaries was worth while

Thanks are due to Mr M Ivri for photographs and skilled observations

Note on Statistical Method

MARGARET P YEKUTIEL, D PHIL Oxfd

The coefficient of association, Q, first suggested by Yule (Yule and Kendall 1947), represents a method for measuring the association between two attributes For a fourfold table of the following form

Attribute	Attribute		Total
	B	b	
A	(AB)	(Ab)	(A)
a	(aB)	(ab)	(a)
Total	(B)	(b)	N

the formula for Q is $Q = \frac{(AB)\,(ab) - (Ab)\,(aB)}{(AB)\,(ab) - (Ab)\,(aB)}$

The value of Q ranges from −1 to +1

In the calculation of Q two values only were used for each variable, hence fundus was classified as (a) normal and stage 1, or (b) stage 2, 3, 4, and diastolic pressure as (a) below 120 mm Hg, or (b) 120 mm Hg or above

Q, while it measures the intensity of association between two attributes, does not measure the statistical significance of the association χ^2 tests were therefore made, and those associations which show a significance at the 0 05 and 0 01 levels are indicated in table IV

PENICILLIN-RESISTANT STAPHYLOCOCCAL PERICARDITIS

E A NIEMAN
M B Lpool, M R C P, D C H
MEDICAL REGISTRAR, ROYAL SOUTHERN HOSPITAL, LIVERPOOL

UNTIL recently the prognosis of staphylococcal septicæmia was very poor, and pericarditis was a formidable complication In a review of suppurative pericarditis, Streider and Sandusky (1941) remarked that the mortality for unoperated patients must approach 100% Since antibiotics were introduced, most acute staphylococcal infections have been cured, but septic pericarditis is still a very serious complication, particularly if the organism is penicillin-resistant

This paper records a case of penicillin-resistant staphylococcal septicæmia with pyopericardium, and discusses the relationship between septic pericarditis and constrictive pericarditis

Results

A man of 49 had a carbuncle on his neck Three weeks later, on April 28, 1955, he was admitted to hospital with general malaise, cough, and hæmoptysis He was very ill with a temperature of 103°F, jaundice, and purpura of both legs There was a discharging carbuncle on his neck, a pustule on his nose, severe cellulitis of the left elbow, and a subcutaneous abscess over the right elbow There were bilateral axillary pleural rubs and coarse crepitations in the right axilla The liver was tender and enlarged three fingers below the costal margin the spleen was tender and palpable There were no cardiac murmurs

A diagnosis of fulminating staphylococcal septicæmia was made, and penicillin ($1^1/_2$ million units 4 hourly) and streptomycin (1 g b d) were given Next day there were many further embolic skin lesions, he complained of headache and blurring of vision and there was neck stiffness on examination

Investigations—Blood culture, sputum culture, and culture of pus from 2 separate subcutaneous abscesses all gave a pure growth of a coagulase positive *Staphylococcus aureus*, resistant to penicillin, but sensitive to erythromycin and oxytetracycline (terramycin) White cell count, 16,500 per c mm (80% polymorphs) Serum bilirubin 3 5 mg per 100 ml Chest radiograph, "patchy pneumonic consolidation both mid zones and in the right lower zone"

On April 30 penicillin and streptomycin were discontinued and erythromycin was begun by mouth (500 mg 6 hourly) Next day he was expectorating foul bloodstained sputum and there were râles in both axillæ A pericardial rub was audible at the cardiac apex and an electrocardiogram (E C G) (fig 1*a*) showed the typical T_2 pattern of pericarditis

On May 6 he was orthopnœic, with striking pulsus paradoxus, increase of cardiac dullness to 1 in to the right of the sternum, and poor quality, rapid heart sounds A radiograph showed a large pericardial effusion and lung *abscesses in the right* middle zone and in the left upper lobe (fig 2*a*)

Pericardial aspiration yielded 300 ml of turbid yellow fluid, on culture this produced a pure growth of *Staph aureus*, resistant to penicillin and sensitive to erythromycin, chlortetracycline (aureomycin), and oxytetracycline Altogether, pericardial aspiration was performed nine times during the succeeding four weeks and staphylococci were grown on each occasion except the last (May 31)

On three occasions 200 mg chlortetracycline was injected into the pericardial sac During this period the patient's

general condition gradually improved Early in June, however, when the heart size had become normal and aspiration impossible, he deteriorated again Sacral œdema and ascites developed and his liver enlarged again to the umbilicus The jugular venous pressure was not raised and there were no basal crepitations Hb 100% (16 g per 100 ml) and serum-proteins 7 g per 100 ml It was considered that constrictive pericarditis was developing at the orifice of the inferior vena cava and possibly also over the right ventricle As he was allergic to mersalyl, acetazolamide ('Diamox ') 250 mg daily was given with a salt-restricted diet He gradually improved again after a stormy three weeks, and improvement continued slowly until he became fit for discharge on Aug 12

Since then fluoroscopy has demonstrated repeatedly that there is virtually no pulsation of the right border of the heart and that pulsation over the left border of the heart is diminished On Sept 20, 1955, a radiograph (fig 2*b*) showed the heart to be of normal size Kymograms (fig 2*c*) confirmed the almost complete absence of visible pulsation over the right cardiac border E C G s (figs 1*b* and *c*) showed negative T_1, T , T_3, T_{AVF}, T_{V_4}, T_{V_6}

On Oct 10, the results of cardiac catheterisation were within normal limits

The patient has since remained well and is now at work as a clerk. He is having no treatment

Discussion

Staphylococcal septicæmia, with or without pericarditis, is usually acute and fulminating and before the advent of antibiotics it was invariably fatal Drainage of the pericardium offered the only hope Shipley and Winslow (1935) stated that " when the pericarditis is an expression of a generalised septic process the field for successful operative intervention seems to be small On the other hand, practically all patients not operated on or treated by aspiration die " With the introduction of antibiotics many cures were reported (Bathurst and Ainsworth 1945, Smith and McHugh 1945, Wise and Shaffer 1945), but since 1949 antibiotic resistance has made staphylococcal infections more difficult to eradicate

In this patient the infecting organism was penicillin-resistant, and erythromycin was used because it is the antibiotic of choice in severe penicillin-resistant infection with pyogenic staphylococci (Martin 1953)

The natural history of healing pyopericardium and its relation to chronic constrictive pericarditis is still uncertain It is widely held that septic pericarditis may give rise in healing to constrictive pericarditis, but the evidence is far from conclusive Paul Wood (1950) states that "it is generally believed that recovery may be followed by constriction but the point is still perhaps uncertain " Pickering (1948) has been unable to find any case report in which a proved septic pericarditis developed constrictive pericarditis in the healed or healing phase Burwell and Flickinger (1935) described a 17-year old negro, with a two-week history of fever and dyspnœa, who presented with tachycardia, venous congestion,

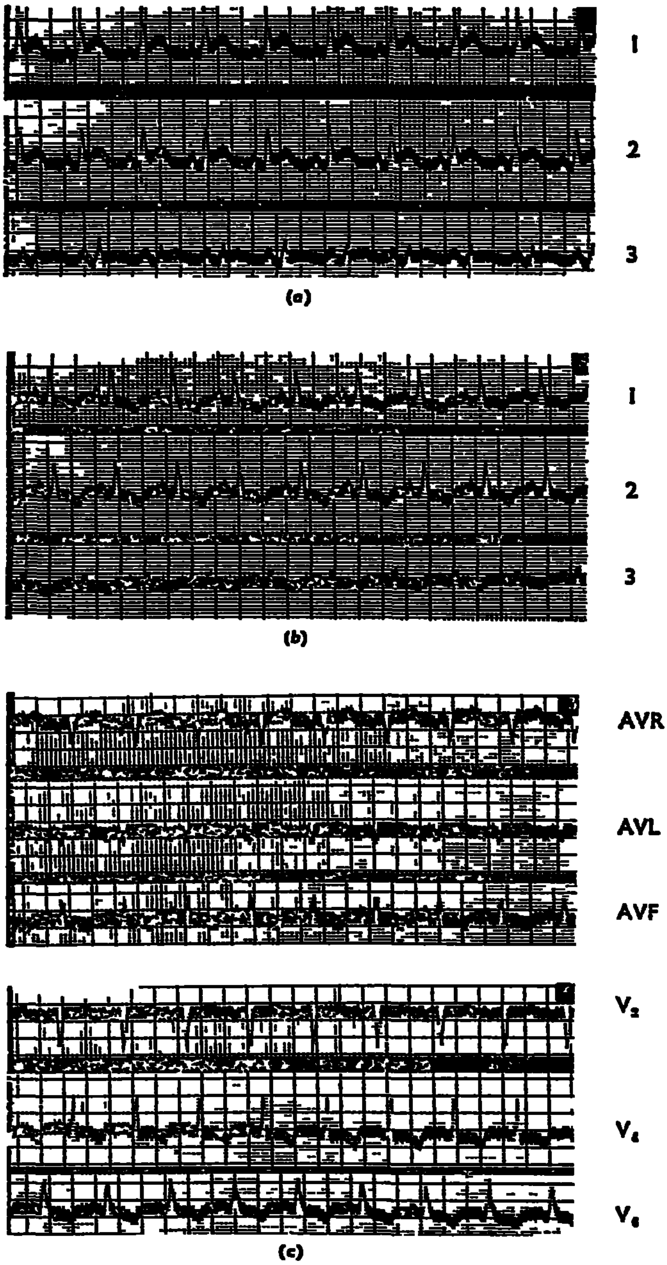

Fig 1—(*a*) Typical T. pattern of pericarditis during acute illness (b) and (c) E E G.s after recovery showing negative T_1, T , T_3, T_{AVF}, T_{V_4}, and T_{V_6}

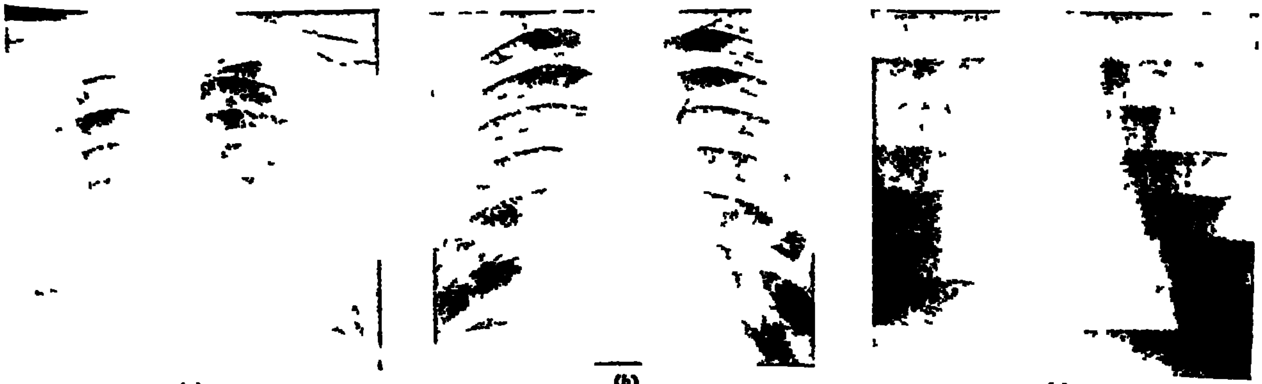

Fig 2—(*a*) Large pericardial effusion and lung abscesses in right middle zone and left upper lobe , (b) normal sized heart 4½ months later but with (c) hardly any pulsation of right cardiac border

dyspnœa, ascites, and bilateral effusions, and in whom fluoroscopy showed a poorly pulsating heart, operation disclosed a pericardium 7 mm thick containing pus from which *Staph aureus* was grown Pickering (1948) remarked that this was not strictly chronic constrictive pericarditis, but rather a septic pericarditis in the late acute or subacute phase The clinical picture and the thickness of the pericardium surely suggest, however, that chronic constrictive pericarditis might well ensue from such a case

More recently, Chambliss et al (1951) believed that out of 61 cases operated on for constrictive pericarditis, 2 had a septic origin, their evidence, however, is very slender. Evans and Jackson (1952) stated categorically that the condition was caused by tuberculosis only I have been unable to find a single case of constrictive pericarditis in the literature up to November, 1956, in which a septic origin was proved

Froment et al (1955) reported 5 cases of septic pericarditis and discussed the natural history Their most interesting case was a true chronic constrictive pericarditis observed for five years and relieved by operation The gross and histological appearances showed no evidence of tuberculosis Five years earlier the patient's symptoms had been preceded by a typical acute osteomyelitis The septic origin of the constrictive pericarditis seems likely, though unproven

In the case recorded here, there is unequivocal evidence of the staphylococcal origin of the pericarditis, of the reduced cardiac pulsation at a time when no fluid was obtainable or demonstrable, and of an episode of obstruction to venous return caused by pericardial constriction That constriction has not recurred means that this case cannot be classed as one of constrictive pericarditis, but further constriction may develop

Summary

Pericarditis developed in a patient with penicillin resistant staphylococcal septicæmia He was cured by oral erythromycin, pericardial aspiration, and intrapericardial chlortetracycline (aureomycin) A subsequent episode was attributed to temporary constrictive pericarditis following healing The relationship between septic pericarditis and constrictive pericarditis is still uncertain.

My thanks are due to Dr H Alstead, deputy physician superintendent of Walton Hospital, Liverpool, under whose care the patient was admitted, for permission to publish this case

Preliminary Communications

EFFECT OF AN AMINE-OXIDASE INHIBITOR ON ARTERIAL AMMONIUM LEVELS IN LIVER DISEASE

THE main sources of the blood-ammonium are said to be the gut, where bacteria form ammonia from nitrogenous substances, and the kidney[1] It also seemed possible that some of the blood ammonium might be derived from amines through the activity of the widely distributed enzyme, amine oxidase If this were so, then administration of an amine oxidase inhibitor might be expected to lower the blood-ammonium, and this effect might be more easily recognised in subjects with a raised blood ammonium Patients with liver-disease, in whom the blood-ammonium is often increased,[2] [3] were therefore investigated The powerful amine-oxidase inhibitor, iproniazid[4] (isopropyl isonicotinic acid hydrazide, 'Marsilid'), was given intravenously in a dose of 5–10 mg per kg body-weight, to 17 patients with liver disease (see table) The fasting arterial ammonium level cited is the mean of two determinations taken thirty minutes apart, the differences being less than 0 2 μg per ml 8 patients had a raised fasting arterial ammonium level ($>$1 μg per ml) and in all there was a significant fall after the iproniazid sixty minutes ($p<0\ 02$) and ninety minutes ($p<0\ 01$) later 9 patients had a normal arterial-ammonium level ($<$1 μg per ml), in 5 administration of iproniazid was followed by a fall, and in 4 the arterial-ammonium level did not change more than 0 1 μg per ml The mean for the whole group showed no significant change

These observations suggest that some of the ammonium responsible for the increased arterial levels in liver-disease is derived from amine degradation The site of this action remains obscure Cardiac, hepatic vein, and renal-vein catheterisation studies have failed to incriminate the lungs, liver, or kidneys as the main site of this ammonia formation (these results will be published in detail elsewhere) This is not surprising, for amine oxidase is widely distributed in vessel walls,[5] and the inhibitory effect is probably general and not confined to any particular organ Amine oxidase is not present in blood, and the addition of iproniazid to blood in vitro did not alter the blood ammonium value

Some of the changes in hepatic coma have been attributed to ammonium toxicity When this investigation was planned, it was thought that iproniazid, by reducing the blood-ammonium level, might prove useful in treating

hepatic coma But 1 patient deteriorated into coma on continuous iproniazid therapy In another patient, an electro encephalogram was recorded continuously after administration of iproniazid Initially, the tracing showed the features of impending hepatic coma,[6] and this was unaltered by the drug, though the arterial-ammonium level fell from 3 8 to 2 7 μg per ml At present iproniazid should not be used in the treatment of hepatic coma Circulatory amines may be more toxic to the brain than ammonium, or deterioration may be due to the other unknown metabolic effects of iproniazid

We wish to thank Roche Products Ltd for advice and generous supplies of 'Marsilid,' and the Medical Research Council for financial support

SOMATIC SEGREGATION OF "INAGGLUTINABLE" ERYTHROCYTES

WHEN human blood is treated with an appropriate antiserum (e g, group-A blood with anti-A antiserum) most of the red cells are agglutinated There remains, however, a small proportion of residual cells which do not agglutinate, even after repeated treatment with an avid antiserum The precise nature of these "inagglutinable" residual cells does not seem to have been investigated

I wish to report the results of three preliminary experiments which I have performed on "inagglutinable" human red cells

(1) In group AB blood, most of the cells which are inagglutinable after repeated treatment with a high-titre anti A antiserum can readily be agglutinated with anti B antiserum

(2) The A receptors on the cells do not seem to be blocked by incomplete antibody Neither Coombs anti globulin reagent nor albumin agglutinates these "inagglutinable" cells

(3) Manipulation of agglutinated red cells does not deprive them of their receptors A fivefold increase of mechanical agitation during the first stage of the Ashby technique does not increase the number of residual cells

These findings are compatible with the occurrence of somatic segregation[1 2] in heterozygous AB cells with the production of clones of B cells Further experiments, which I have so far been unable to perform, are needed to show to what extent, if any, somatic segregation is the explanation for "inagglutinable" erythrocytes

It must be shown that

(*a*) In group AB blood most of the cells inagglutinable after repeated treatment with high-titre anti-B antiserum are readily agglutinable with anti A antiserum

(*b*) Homozygous individuals (AA or BB) have far fewer residual cells than heterozygous (AO, AB, or BO) individuals

(*c*) The distribution of residual cell counts on a series of heterozygous individuals shows wild fluctuations from the mean as a result of the variation in the stage of embryonic development at which somatic segregation occurred

(*d*) In a series of group A_1B subjects there is a positive correlation between the residual cell counts after treating separate portions of each individual's blood with anti A and anti-B antisera With perfect antisera the expectation is that the two residual types should appear in equal proportion in any *one* individual

I submit these preliminary observations in the hope that they may be of interest to workers in the field of immunohæmatology who have at hand individuals of known genotype and adequate supplies of appropriate antisera

New Inventions

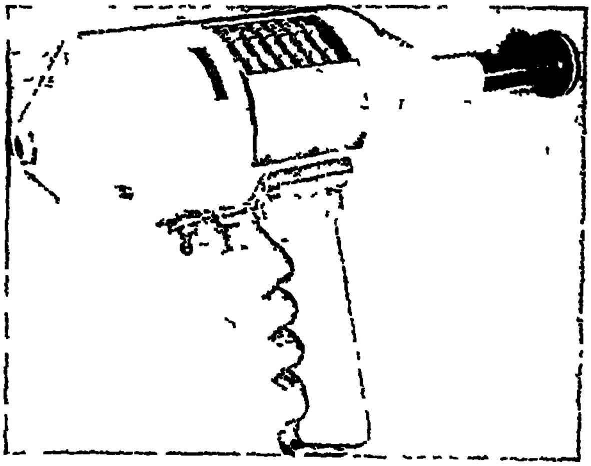
A HAND TINTOMETER FOR RADIOLOGICAL AND DERMATOLOGICAL WORK*

IN radiological work it is often desirable to measure and record radiation reactions of the skin In the past the lack of an exact method of measurement has greatly hindered investigations in this field In dermatology the need of quantitative evaluation of colour changes has long been felt Photometric methods have been tried but are unsatisfactory in that they do not record tone or hue but only intensity of light The instrument here illustrated was developed in collaboration with Messrs G J Chamberlin and F J Heath, Lovibond Tintometer Ltd, Salisbury, to whom we are indebted

In viewing, a circular split field is seen, one segment being the sample under examination and the other a standard white surface, both being illuminated equally with three electric bulbs inside the instrument By means of rotatable discs a graded series of 'Lovibond Glass Standards,' coloured red, yellow, and blue, can be interposed between the source of illumination and the white surface, the combination being adjusted until the two segments are matched in tone and intensity The values of the sample are defined in terms of the amount of each of the three filters required for colour match Provision is also made for insertion of neutral tints over the sample, if this is excessively bright

Practice is required to use the instrument to the best advantage, and it is advisable always to use it under the same conditions of room lighting As colour is a subjective sensation, the same person should make all the measurements in one series of experiments

The advantages of the method are as follows (1) the original tint can be reconstructed at any time, enabling comparison to be made with other samples or with the same sample at a later date, (2) it is possible to convert



the Lovibond values to international units, and (3) the *Lovibond units being known and accepted in most countries, the significance of the values recorded at any centre is not so restricted* as would be the case with other methods

The instrument has been in use in the department of radiotherapy in this hospital for more than three years and has proved very useful in radiobiological and dermatological work and as a research tool

In plastic surgery it has proved to be a boon as it dispenses with the need for repeated attendances for colour matching of patients for whom prostheses (artificial noses or ears) are prepared

* The instrument was exhibited at the Eighth International Congress of Radiology in Mexico City (July 1956)

Medical Societies

BRITISH ORTHOPÆDIC ASSOCIATION

THE Robert Jones centenary meeting of the association was held at Shrewsbury and Oswestry on May 9–11, under the presidency of Mr PHILIP WILES.

Spinal Fusion for Scoliosis

Mr I W WINCHESTER (Oswestry) had reviewed the results in 66 cases considered suitable for fusion in the past twenty years at Oswestry—7% of the patients seen with scoliosis. Fusion was done to diminish final deformity or hold correction, to stabilise the spine, and to prevent pain. The Risser jacket had now been abandoned for the Abbott method. After fusion, patients spent three to six months lying and a further six months ambulatory in a jacket. 11 cases followed for less that two years were excluded, of the remainder, 33 were idiopathic, 11 congenital, and 11 paralytic. 80% had relapsed, including almost all those where some previous correction of the curve had been obtained. As a proportion of the original curve, the average original correction was 38%, the final maintained correction 14%. Mr Winchester accounted for this relapse rate under four headings: (1) inaccurate measurements, (2) failure to produce adequate compensatory curves (the danger of over compensation was probably theoretical only), (3) subsequent growth, associated with failure to extend the fusion into the compensatory curves, and (4) development of pseudarthroses, although none were detected in this series. He concluded that correction of rotation was a vital factor in preventing relapse, and that the object of plaster correction was to increase the compensatory curves rather than to correct the primary curve.

Posterior Dislocation of the Shoulder

Mr W GISSANE (Birmingham) said that Astley Cooper had described posterior dislocation as easily diagnosed, but in fact it was rare and the diagnosis often missed. Fractures of the humeral head (either a coronal split or a "pond" fracture), from contact with the posterior rim of the glenoid, were common and produced harsh crepitus. Dissection and operation had shown that the glenoid labrum remained intact, the capsule being torn close to it. The dislocation was due to an internal rotation force, the posterior glenoid margin might also be fractured. Subscapularis remained intact. The lesion had been explored through a posterior incision, splitting the posterior third of the deltoid and dividing infraspinatus. Fractures of the head had been wired, the wire lying under the articular cartilage, and the dislocation reduced by external rotation of the arm. The patient could return to work in three months, though full movement might take a further year to recover.

Sir REGINALD WATSON JONES said that the essential point of reduction was external rotation and that the arm must be splinted for three weeks in external rotation to prevent recurrence. Mr GISSANE denied that fixation in external rotation was necessary after open reduction and repair, the shoulder was perfectly stable in a sling.

Epiphyseal Stapling in Knock-knee

Mr A E PRITCHARD (Liverpool) spoke on stapling of the lower femoral epiphysis in idiopathic knock knee. He had studied 26 patients treated by Mr Robert Roaf at Liverpool and by the surgeons of the Robert Jones and Agnes Hunt Orthopædic Hospital. Conservative treatment had failed to benefit these children, who were all 8 years of age or more and almost all overweight. He maintained that surgery was occasionally indicated in this type of patient, and believed that epiphyseal stapling was superior to supracondylar osteotomy because (1) the cosmetic result was better, (2) the period in hospital was shorter, and (3) nursing was much easier. He described the technique and emphasised that no stripping of periosteum was necessary, and that it was probably unnecessary to staple the upper tibial epiphysis as well. Three staples must be used, and should be left in place until there was slight bow leg. It was impossible to predict the time required for correction in each individual: this varied from five to twenty-one months. The results were excellent in 24, 2 relapsed, 1 child was left with some loss of knee movement. After removal of staples there was a sudden growth spurt followed by normal epiphyseal growth. In no instance had this failed to follow. Tribute was paid to Dr Walter Blount, who had pioneered the procedure.

Sir REGINALD WATSON JONES said that in the past twenty years he had never found it necessary to operate for knock knee. Correction always took place within one to three years if Robert Jones's principle was followed, shoes with inner wedges on the crooked heel and sole must be worn constantly—even to the bathroom.

Mr W SAYLE CREER (Salford) denied that wedges always cured knock knee, and thought that the use of a night splint was essential. Stapling operations were liable to leave swollen knees with ugly scars, and he preferred a supracondylar osteotomy when necessary.

Mr ROBERT ROAF (Oswestry) said that all the cases discussed by Mr Pritchard had been deteriorating despite conservative treatment. There was no difficulty in removing the staples as long as they were not buried under the periosteum. He now rarely felt it necessary to staple the tibia also.

Mr H OSMOND CLARKE thought that splints were useless and inflicted psychological trauma on the child. His experience led him to use staples less and less in this condition.

Immunity Factors in Bone Homografts

Mr J CHALMERS reported experiments undertaken to see whether bone homografts participate in a tissue immunity reaction. Bone homografts to a muscle site in rats gave rise to an early phase of new bone formation which was arrested at ten days, the new bone later died. After several weeks, a second phase of new bone growth appeared in relation to the graft. If the rat had been immunised by a skin graft from the same donor, there was no early phase of new bone growth. If the homograft had been killed by freeze drying, the early phase did not occur, but the second phase did in a few instances. It was concluded that the early phase arose from osteogenic cells carried over with the graft, which became the victim of an immune response by the host. The second phase was due to metaplastic induction in the host connective tissue cells.

Further evidence was provided by experiments in which skin homografts were carried out in animals which had been previously grafted by fresh bone homografts from the same donors. The skin grafts were rejected early (at six days). When the bone homograft had previously been treated by freeze drying, subsequent skin homografts survived the normal span of eleven days. This showed that bone contained tissue antigens, and that both bone and skin had antigens in common. These antigens were inactivated by freeze drying.

Bone bank homograft was unlikely to prove inferior clinically to fresh homograft, for neither could contribute living cells. As dead graft did not stimulate immunity, some other process than a tissue immunity reaction must be responsible for the differences in behaviour between bank homograft and fresh autograft.

Dr PAUL CURTISS (Cleveland) held that, since no circulating antibody active against a homograft had been identified, immunisation was not yet proven.

Atlanto-axial Dislocation in Spondylitis

Mr D W PURSER and Dr J SHARP (Manchester) said that, although it was very rarely reported in the literature, they had seen 40 cases of spontaneous atlanto axial dislocation—17 in ankylosing spondylitis and 23 in rheumatoid arthritis. Tetraplegia might follow. The diagnosis depended on flexion extension radiographs, the lateral view revealing the forward shift as well as the angulation of the atlas on flexion which was associated with rupture of the transverse ligament. In ankylosing spondylitis it was usually seen in long standing (and often still active) cases, many with severe spinal flexion deformity and some with signs of cord involvement. The head was tilted forwards with flattening of the angle between neck and occiput. Pain made worse by coughing was a common symptom. Radiotherapy gave no relief. The onset of neurological symptoms might be very sudden, and the presence of lesions in the lower cervical spine might complicate the diagnostic problem. Reduction and fixation by bone grafting from occiput to axis usually led to almost complete recovery. Some patients stabilised spontaneously. In rheumatoid arthritis a painful click was often present on movement, but neurological involvement was much less common. Nerve lesions or severe pain were held to be an absolute indication for operation. Reduction was attained, and maintained during operation, by traction with skull callipers inserted further forwards than usual. Three weeks after operation, plaster was applied, embodying the skull callipers, and maintained until union was sound.

Mr. J. H. ANNAN (Huddersfield) demonstrated radiographs of a similar case with gross displacement when the patient was erect but which reduced spontaneously in dorsal decubitus.

Non-union of Humeral Condyle

Mr. C. C. JEFFERY (Exeter) said that of 13 cases of non-union of the lateral condyle of the humerus, 10 had resulted from minor displacements and 3 had followed open reduction and soft-tissue suture of major displacements. Some cases of initially slight displacement progressed to non-union with increasing deformity, grossly distorted elbows, and sometimes delayed ulnar palsy.

Open reductions should be stabilised by internal fixation with a *stainless-steel screw to maintain exact reposition*; imperfect closed reductions should be critically assessed with a bias towards open reduction and screwing; union must be established unequivocally by radiographs; and where union was delayed or where non-union was established without significant displacement, a hole should be drilled through the portion of diaphysis which had separated along with the displaced epiphysis and on into the humeral diaphysis. The resulting cavity was packed with iliac cancellous bone. This operation had resulted in bony union, minimising deformity, in the 3 cases of non-union which arose under supervision.

Poliomyelitis Vaccination

Prof. C. H. STUART-HARRIS (Sheffield) said that some people had argued against any preliminary clinical trial of poliomyelitis vaccine by analogy with the history of diphtheria immunisation, and on the *grounds that proof of the vaccine's* antigenicity in monkeys was sufficient evidence of its being beneficial, that large-scale experiment on children was morally unjustifiable, and that in any case the American trial would soon produce the evidence required. But after the disaster in the United States the British vaccine was modified and the American results were no longer applicable. Therefore the British vaccine was introduced in such a way that its effect could be measured. An appeal for volunteers yielded 30% of the 6,000,000 children aged 1–9 years. The fact that the vaccine was so scarce enabled controls, as far as possible free from bias, to be obtained from volunteers who could not be inoculated; the giving of an inert inoculation to this group—the ideal method—was not practicable.

All cases of poliomyelitis, both paralytic and non-paralytic, notified within the ages 1–9 were reported to the M.R.C. statistical unit, and for all registered children among them clinical reports were requested three weeks and three to five months later. These reports did not answer the question whether inoculation influenced infection by the virus (i.e., reduced its ability to infect the gut)—a matter to be settled only by laboratory tests. Type-I virus was found in more than 80% of cases, thus providing an adequate field test of the effectiveness of the type-I strain used in the British vaccine. The incidence of immediate local reaction was very low because of the small protein content, and sensitisation to antibiotics was very unlikely. Immunisation to monkey protein was possible, but tests for antibodies arising from the presence of Rh antigen and for nephritis from monkey-kidney material had all proved negative. The exclusion of live virus by stringent safety tests would prevent direct infection; the possibility that latent poliomyelitis in the child might be provoked by the injection was under consideration.

Dr. W. L. M. PERRY said that the virus was incubated in a medium containing a tissue-culture of monkey renal cortical cells; after filtration, the resulting suspension of living virus was treated with formalin for fourteen days.

In the United States disaster with the Cutter vaccine, virus was isolated from about half of the 200 cases of poliomyelitis, and of these isolations all but one were of the type I Mahoney strain. The presence of living virus in the offending batches of vaccine could be demonstrated easily only in tests on cortisone-treated monkeys, most of the tests in tissue-cultures of renal cells proving negative. The monkey tests demonstrated the presence in the vaccine of living virus of all three types. This discrepancy had never been explained, and was the main reason for the rejection of the Mahoney strain of type I for use in the British vaccine. In Britain tests were made both by the makers and by the M.R.C. In each laboratory nearly 2 litres from each batch was cultured and subcultured over a five-week period, and tests were also carried out by intracerebral, intraspinal, and intramuscular injection in both rhesus and cynomolgus monkeys, the latter being more sensitive than the former. Tests for antigenicity were made in monkeys after three injections at weekly intervals, the serum antibody content being estimated by its capacity to neutralise living virus added to tissue-cultures.

Prof. G. W. A. DICK (Belfast) emphasised that type I virus was responsible for most cases of paralysis. The antibodies produced by each type were specific. The object of work with live viruses had been to reproduce the immunity associated with natural infections, with the added advantage that the vaccine could be taken by mouth.

An attenuated type-II virus strain (originally used by Koprowski) was considered suitable because it never produced paralysis when inoculated intracerebrally in monkeys and was non-cytopathogenic. It was tried in 190 children and type-II antibodies developed in 77%. Unfortunately it was found that the virus was excreted by all subjects who developed antibody. Furthermore the excreted virus was cytopathogenic, and caused paralysis in inoculated monkeys. Because of the potential danger of this strain further study of it was abandoned. Experience with a type-I (SM) strain was similar.

There was at present no evidence that three injections of a good Salk-type vaccine produced an immunity inferior to that produced by attenuated strains, and one line of future research should be directed towards developing a purified dead-virus preparation of high antigenicity rather than towards the present types of live-virus vaccines.

Calcinosis Circumscripta

Dr. R. W. BAILEY (Los Angeles) divided calcinosis into two groups: (1) calcinosis circumscripta, usually seen in women and associated with scleroderma, sclerodactyly, and Raynaud's syndrome; and (2) calcinosis universalis, often an affection of children. Abnormal calcium and phosphorus metabolism, local failure of circulation, and some endocrine upset associated with the menopause had all been considered in the ætiology, but without clear-cut evidence. He reported a case in a woman of 63, whose hands and elbows were chiefly affected. She was in slightly positive calcium balance; phosphatase and other laboratory studies were normal. Biopsy showed that fascial planes and muscles were affected with intramuscular collagenous degeneration and thinning of the overlying skin. He had tried the effect of sodium edetate ('Versene') in this patient in the hope that it might bind with the calcium in the deposits and help disrupt them. Although calcium output in the urine was increased, there was no clinical change, nor reduction in the calcium percentage in the ashed deposits. The drug caused auricular fibrillation, which ceased on its withdrawal. He concluded that calcinosis was not a general metabolic disease but a local change. There was no evidence of preferential removal of calcium from the deposits. He postulated that in these cases something was lost from the cells which normally protected them from calcification and thought that future work should aim at further understanding of histochemistry and cell metabolism.

Mr. H. J. SEDDON commented that similar calcification was seen in Volkmann's ischæmic contracture.

Idiopathic Pes Cavus

Mr. J. N. ASTON had reviewed 755 cases of idiopathic pes cavus from hospital records. The information thus obtained was limited, and there was a bias in favour of the severer case, whatever aspect was considered.

Pes cavus did not often present under the age of 5 years, reached a peak between 9 and 13, and then fell off again. Males were affected more often, earlier, and (in the young) more severely, than *females*. This early male preponderance was not seen in the progressive cases, which did not seem to present any younger than the average.

Those with varus of the heel did badly; those with valgus did well. Clawing was the commonest individual feature, and those with either clawing or dropping of the 1st metatarsal head did not do as well as those in whom it was not severe. Forefoot varus and asymmetry between the feet seemed to make no difference to the outcome.

Some relationship seemed probable between pes cavus and spina bifida occulta. A laminar defect was found in 52 of 104 cases radiographed against about 18% in normal people; it did not seem to be associated with a bad prognosis.

Reviews of Books

Essentials of Fluid Balance

D A K BLACK, M D, F R C P, reader in medicine, University of Manchester Oxford Blackwell Scientific Publications 1957 Pp 127 18s 6d

IN less than 100 pages, Dr Black has summarised present knowledge of fluid balance, covering the metabolism of water, sodium, and potassium, and the acid-base balance In a short appendix he discusses some special problems This is concentrated fare, but it demonstrates well how knowledge gained from physiology, medicine, surgery, and therapeutics can be drawn together into an easily comprehensible story No amount of writing can encompass all the clinical problems, and attempts to do so have often been tedious and sometimes misleading This book provides the essential information on which to base decisions about particular problems It should prevent many misconceptions the serious student will enjoy it, and the clinician may well turn to it for help when some larger work has failed him

Dr Black brings out the limitations of treatment, where knowledge is still wanting He does not believe in rule-of-thumb methods, for here, perhaps even more than in other subjects, treatment is a matter of understanding and not of dogma, but in a final short chapter, aptly headed "an approach to treatment," he gives some guidance on how to apply what is known Some readers might have liked to see an example of a workable chart for the day-to-day records on which treatment should be based, but, as is his custom, Dr Black indicates where the information may easily be found, and many people may prefer to devise a chart of their own

The style is concise, forceful, and often witty An occasional ambiguity interrupts the reader's progress in the earlier parts of the book, on the other hand, when he comes to the chapter on potassium he is treated to a masterly presentation There is an up-to-date source of selected references, and the delay between writing and publication has been remarkably short Both students and teachers will be attracted and rewarded by Dr Black's skilful handling of his subject

Connaissance élémentaire du rhumatisme

S DE SEZE and M MAITRE Paris Expansion Scientifique Française 1957 Pp 273 2800 francs

THIS lively and attractive introduction to the rheumatic disorders has been written by Professor de Seze (with the aid of M Maurice Maitre's lucid diagrams) primarily to instruct nurses, physiotherapists, and occupational therapists There is, however, sufficient detail to make it a useful introduction for students and doctors, who would find the many excellently reproduced radiographs and clinical photographs particularly helpful In the section on treatment the emphasis is often different from that usual in this country Thus, sex hormones are given an important place in the treatment of degenerative joint disease, and in rheumatoid arthritis cortisone and its relations are dealt with first and at length, overshadowing the subsequent description of the basic regimen of rest, splinting, and exercises

Surgeon's Journey

J JOHNSTON ABRAHAM London Heinemann 1957 Pp 441 25s

IF any book called loudly for a sequel it was Mr Johnston Abraham's *The Surgeon's Log*, published in 1911, now in its 30th edition, and translated into several tongues This new book tells of his life before and since the casual voyage which gave him quite unexpected fame and our language one of the best of travel books

A boyhood in County Londonderry was followed by professional education at Trinity College, Dublin, in the palmy days of Mahaffy *et al* He reached consulting practice in London by the haphazard and strenuous route usually followed in those days Between 1914 and 1918 he served first in the Serbian army and then in our own in Egypt and Palestine Few accounts of th medical services in war are at once so readable and instructive In the years which followed the war it was his delight to write of his profession Though the laity favour the gripping works of "James Harpole," it is his life of Lettsom which has pleased the author most and given him his considerable repute as a medical historian As a publisher he has done his best to hel other medical authors But with all these distractio his life has centred on his surgical practice and hi hospitals, the Princess Beatrice and the Lock, whos obituary notice he writes with candour and charity

This is the urbane story of a man who has seen the best of life in London, social and professional, and enjoyed every minute of it In his native Coleraine they will be saying, no doubt, that Jamie Abraham is a great crack and a sound medical doctor forbye—and so he is

Left-handedness

Laterality Characteristics and their Educational Implications MARGARET M CLARK, M A, PH D, the Scottish Council for Research in Education. London University of London Press 1957 Pp 212 15s

THIS is an excellent account of a fundamental educational problem—the detection and training of left-handed children Dr Clark gives a brief, but just, review of the literature, a clear picture of the tests for dominant laterality, and a description of her own research Her book will be useful to teachers, educational psychologists, and school medical officers Any doctor who is in the habit of diagnosing "crossed-laterality" as a cause of clinical symptoms should read the book—and he will receive a salutary shock

The Bright Countenance

A Personal Biography of Walter Morley Fletcher MAISIE FLETCHER London Hodder & Stoughton 1957 Pp 351 25s

THIS biography began as a family record Written by Lady Fletcher, it was originally intended for Sir Walter's grandchildren, and, though it has now been made available to the public, the family intimacy of the writing has been retained The text includes long extracts from his letters and other writings on many subjects

The book begins with a delightful short biographical foreword by the late M R James and ends with a 40-page supplement in which Sir Arthur MacNalty describes Fletcher's contributions to physiology and his work for the Medical Research Committee and later for the Medical Research Council A great deal was achieved by these bodies under his wise guidance, but, as Sir Arthur points out, a whole volume would be needed to record the extraordinary progress of those eventful years

---

Textbook of Orthopædic Medicine (3rd ed Vol I *Diagnosis of Soft Tissue Lesions* London Cassell 1957 Pp 711 45s)—Anyone who practises orthopædics soon discovers that many of his patients suffer from maladies which are not illustrated in any museum of pathology Their radiographs are normal, their laboratory investigations negative—and their treatment correspondingly difficult Dr *James* Cyriax has provided a guide to this dark hinterland in surgery From its pages the practitioner may learn to diagnose with confidence such conditions as "tennis elbow"—and even to distinguish between at least four distinct varieties of the disease Far from being nonplussed when confronted by a case of acute sciatica, he can now choose his treatment from more than forty thoughtful pages on its management Dr Cyriax is convincing and interesting on such debatable topics, but his excursions into the more familiar field of surgical orthopædics are less successful, and here clarity is sometimes sacrificed to brevity We are sorry to see that Georg Clemens Perthes is again poorly remembered in "Perthé's disease," though Dr Cyriax is by no means the first to add the accent and the apostrophe The volume is clearly based on long and careful thought, and all who undertake to relieve the painful and common conditions Dr Cyriax describes will be glad to have his advice to hand

THE LANCET

LONDON SATURDAY, JUNE 29, 1957

Cigarettes

> "We are constantly deluded by language We say a person dies of a cancer The truth must be that a person dies of the causes of cancer, and the cancer is not the cause, but the mode of dying'—WILLIAM LAMBE 1815[1]

THE evidence that heavy cigarette-smoking causes cancer and hence death has become increasingly difficult to ignore The Medical Research Council's statement set out on p 1345 summarises the facts clearly and concisely, and concludes with the important statement that ' In the opinion of the Council the most reasonable interpretation of this evidence is that the relationship is one of direct cause and effect " This conclusion accords with the view of most who are familiar with the mass of detailed evidence accumulated in the past seven years not least through the careful and convincing studies of Prof A BRADFORD HILL, F R S and Dr RICHARD DOLL The unhurried verdict of an impartial scientific body such as the M R C cannot but command respect and must make every thoughtful person reconsider the criticisms by the Tobacco Manufacturers' Standing Committee[2] This committee discounts the suggestion of cause and effect because it derives from observations rather than from strictly controlled human experimentation on randomly selected population groups and because, so far, no very convincing support has come from the laboratory The limitations of observational data have long been well known to epidemiologists, but should SNOW have waited for the discovery of the cholera vibrio before persuading Londoners not to drink their own sewage ? As the tobacco manufacturers have implied, atmospheric pollution may be a factor in the causation of cancer of the lung, but its incrimination, like the association of genotype and disease, rests equally on observed correlations In the urgent defence of the public health we should base action on the best evidence currently available

Whatever the reaction to the evidence we already have, all will agree that more would be welcome In 1954 the British Tobacco Manufacturers Association gave £250,000 to the Medical Research Council, of which £69,000 had been spent by the end of last October This may seem a comparatively small amount for such an important subject The work of the council is, however increasing, as its latest annual report, published this week, makes clear It has provided, with the help of the fund laboratory facilities and staff (in the University of Exeter) for a new carcinogenic-substances research group and has set up other research groups concerned with atmospheric pollution (at St Bartholomew's Hospital) and with epidemiological research in respiratory diseases (in the University of Sheffield) In addition grants have been made to individuals in universities, hospitals, and elsewhere

It would be unreasonable to expect the people or the Government to take kindly to the idea of reducing cigarette-smoking, for this is both a widespread pleasure and the source of immense State revenue and of an important element in international trade It may reasonably be argued that the citizen should be free to engage in the pleasures he chooses, provided he does not harm others, but all smokers and potential smokers should at least be aware of the extent of the risk in smoking cigarettes heavily, and this information can be conveyed best (and perhaps only) with the Government's help Measures aimed at direct control of smoking, even were this desirable, would have little chance of success No such measure could succeed without the approval of a large majority of the people, and it seems unlikely that approval on this scale would be forthcoming (Almost to a man, the large smoking public has more than once shrugged off indirect control applied through steep rises in the tax on tobacco) Yet the responsibility of Government and people, whether smokers or not, cannot end with subsidising research and publicising hazards it should extend to discouraging young people from taking up the habit of smoking cigarettes A middle-aged cigarette-smoker with a chronic cough may be moved by the fear of cancer to reduce his smoking or give it up, but we cannot expect a young person to be deterred by a risk that is apparently so remote and among adolescents smoking seems in fact to be lamentably common[3,4] Youngsters are unlikely to be influenced so much by lectures, pamphlets, and the advice of adults as by fashion among those to whom they look for an example Smoking is very much a matter of fashion, and if the large loss of life due to cigarettes is to be reduced the fashion, especially among young people, must be changed Such a change (as is clear from the article on p 1348 of this issue) does not necessarily require legislation, and closer study of the social history of tobacco might be rewarding In any event it is doubtful whether tobacco habits can be changed rapidly so long as the reformer's modest voice has to be pitted against the power of modern advertisements, but organisations, such as the British Broadcasting Corporation, that do not depend on advertising revenue could do much to counter commercial propaganda, and the cinema might shape tobacco habits just as it shapes hair styles In addition, fuller use should be made of existing legislation the law against selling tobacco to young people is often administered with the utmost laxity

It would be unrealistic as well as arrogant to suppose that cigarette-smoking can or should be forbidden the aim should rather be to influence the heavy smoker to modify his habit This modification might take two forms first, replacement of the cigarette by the less dangerous pipe or cigar, and, secondly, reduction in the amount of tobacco used The evidence suggests that the temperate cigarette-smoker, who confines himself to, say, one after each meal or to two or three in the evening, runs an appreciably lower risk Two hundred years ago "drunkenness was the acknowledged national vice of Englishmen of all classes"[5] Today, to drink whisky from a hip-flask in a suburban train on the way to work is socially unacceptable Maybe to smoke a cigarette at such a time will in due course also be deemed a social impropriety If so, the community will be the healthier

The Newborn Infant's Oxygen-supply

The newborn infant, deprived of the placental circulation, will die unless by his own efforts he can produce and maintain a higher level of oxygenation than prevailed in the later phases of intra-uterine life The immediate adjustments of post-natal life are directed to this end and are primarily concerned with establishing adequate pulmonary ventilation and ensuring that the brain, rather than the liver, receives the best-oxygenated blood

The fundamental work of Barcroft[6] showed that in pre-natal life the fœtus elaborates the central nervous organisation required for breathing, which normally is inhibited until required for pulmonary respiration Release from inhibition occurs either because of the inflow of new sensory stimuli at birth or by hypoxic depression of the inhibitory centres Acheson et al[7] have extended this work using, like Barcroft, the sheep In a study of oxygen consumption in fœtal and newborn sheep they have shown that there exists a remarkable, but limited, capacity to adjust the oxygen need in relation to the supply In the latter half of pregnancy adequate oxygenation can be maintained only by great increases in umbilical blood-flow If the placenta is insufficient or the compensatory mechanisms in the fœtus fail, the survival of the fœtus depends entirely on its tolerance to anoxia That similar mechanisms operate in human pregnancy seems likely from the work of Walker[8] and Rachel MacKay,[9] who have shown a progressive fall in oxygen saturation of the umbilical-cord blood as pregnancy proceeds to term and, especially, beyond A similar fall is found when pregnancy is complicated by pre-eclamptic toxæmia Some of the clinical facets of placental insufficiency have been discussed by Randall[10]

Placental circulatory failure with decompensation of the fœtus will cause, in severe cases, intra-uterine death Lesser degrees of hypoxia may initiate intra-uterine gasping movements which, if associated with meconium-stained liquor amnii, produce asphyxia and meconium pneumonitis The anoxic infant is born with an inadequate oxygen reserve and a depressed nervous system—two factors which greatly decrease its ability to attain adequate pulmonary ventilation More acute lowering of fœtal oxygenation is found in cases of abnormal delivery, interruptions of placental blood-flow, as in placenta prævia and prolapsed cord, and interference with the oxygen-supply to the placenta by general or spinal anæsthesia Henderson et al[11] point out that, while all these factors produce a measurable lowering of umbilical-vein oxygen saturation, this is not necessarily a good guide to the clinical state of the infant Some infants at birth may survive with extremely low cord-oxygen saturations, whereas others with mildly reduced oxygen saturations are severely asphyxiated This is to be expected in view of the limited value of a single sampling of cord blood and the many traumatic and chemical factors which influence the first hours of a baby's life

After birth the majority of infants rapidly attain a near-adult arterial oxygen saturation[12] Shields and Taylor[13] have shown that infants born after complications of pregnancy, heavy maternal analgesia, or operative delivery are considerably slower in achieving a normal saturation, determined by a continuous recording ear oximeter Further studies on the lines of those reported by Cross et al[14] are needed in order to elucidate the special metabolism of the newborn and its powers of survival in low oxygen levels Possibly other factors are more important than oxygen saturation in determining the clinical condition of the newborn and the eventual prognosis One of the other factors is the circulatory status of the newborn The neonatal circulation plays an important part in producing lung expansion and also ensures preferential oxygenation of the brain Adams and Lind,[15] by cardiac catheterisation, have demonstrated directly the persistence of a patent ductus arteriosus with a predominantly left-to right shunt in the first few days of life Dr Gunther[16] has attempted to relate the complicated circulatory adjustments after birth with the changes in blood-volume consequent on occlusion of the cord and the later development of pulmonary syndrome Early clamping of the cord or elevation of the infant while the cord is still attached to an atonic uterus will deprive the infant of much of his blood-volume This will be of greatest importance in premature babies, who have a relatively larger proportion of blood in the placenta, and in babies delivered by cæsarean section It is just these two classes of infants that are susceptible to pulmonary syndrome or, as it is better known, hyaline membrane disease Brown[17] has already drawn attention to the possible connection between early clamping of the cord and the onset of hyaline membrane disease So far, the arguments for this association are largely theoretical Dr Bonham Carter,[18] summarising recent advances in this field, has ingeniously related the changes immediately after birth with the respiratory difficulties of early neonatal life It should not be difficult to devise a controlled study to demonstrate this relationship It is now generally, although not universally, accepted that hyaline membranes are formed from pulmonary exudate, probably as a result of pulmonary congestion or hypertension[19] Early clamping of the cord might well lead to pulmonary hypertension as the rise in systemic blood-pressure consequent on the increased peripheral resistance will be transmitted via the patent ductus arteriosus to the largely unopened pulmonary vessels It is more difficult to see how the reduced blood-volume consequent upon siphonage would operate Certainly, expansion of the lungs might be delayed, but the picture of hyaline membrane is one of obstructive dyspnœa, emphysema, and secondary collapse rather than of primary atelectasis Nor do infants born exsanguinated from acute blood-loss show clinical or pathological evidence of hyaline membrane

Whatever the truth concerning this hypothesis, it is salutary to review continually the management of the newborn in relation to newly discovered physiological facts The tragedies of retrolental fibroplasia and of kernicterus of prematurity due to excessive dosage with a vitamin-K analogue are stern reminders that we fail to do so at the infant's peril

Second Thoughts on Anticoagulant Treatment for Coronary Disease

JUST over a year ago we reviewed current views on the value of anticoagulant treatment in acute coronary disease [1] and drew attention to the conflict of opinion between those who, like GILCHRIST in Edinburgh and IRVING WRIGHT in New York, believed that every patient should be given the benefit of anticoagulant treatment, and those who, like RUSSEK and ZOHMAN, consider that such treatment should be reserved for the "poor risk" patient The choice between these two views is important because, if the first group are right, it would be logical to send to hospital every patient who is fit to be moved so that anticoagulant treatment can be begun without delay, whereas if the second group are correct it would be best for the "good risk" patients to be kept at home The burden of the anticoagulant treatment on hospital accommodation and laboratory facilities has already become considerable and coronary thrombosis is now one of the commoner causes for admission to hospital

The two papers from Oxford by Dr HONEY and Dr TRUELOVE which appeared in two of our recent issues [2] bear directly on this problem, since they have examined afresh the question whether anticoagulant treatment does in fact improve the prognosis of acute myocardial infarction, and how far the large expenditure of time, energy, and money on the admission to hospital and the laboratory control of treatment is justified by results They have made an elaborate analysis of the results of 543 admissions (involving 506 patients) to the Radcliffe Infirmary at Oxford in the years 1940–54 They took an arbitrary time of eight weeks from onset to represent the acute phase, and succeeded in tracing all but 1 of the 348 patients who had survived beyond this phase The period of the survey spans the introduction of anticoagulant treatment at the hospital in 1948, and since 1951 3 out of every 4 patients have received this treatment In their series of patients there were twice as many men as women, two-thirds of the men were aged 50–70, two-thirds of the women were aged 60–80 Women of equal age have a better chance of survival than men, but fatality increases with advancing years and these two opposed effects cancelled out, so it was not necessary to differentiate between the sexes Surprisingly, there was no appreciable difference in mortality-rate between those patients who were admitted in their first attack and those who had a clear-cut history of a previous infarction The fatality-rate was unaffected by a previous history of angina of effort, or hypertension It seems to make no difference whether the attack occurs during exertion or comes on at rest The really bad prognostic findings are, as so many physicians have emphasised, the presence of early shock and hypotension

HONEY and TRUELOVE have examined very critically the data about their patients treated or not treated with anticoagulants and conclude that their figures show that anticoagulants "have had only a small beneficial effect on the fatality of myocardial infarction" They calculate that in the period 1952–54, when anticoagulants were extensively used, out of 263 admissions only 11 lives were saved by this treatment—i e, the mortality was 11 lives less than would have been expected from previous experience with 263 cases of the same clinical characteristics Examination of post-mortem records showed very clearly that the reduction in deaths accompanying anticoagulant treatment was largely due to the elimination of pulmonary embolism as a cause of death Before anticoagulants were used, 6% of the patients who survived the first forty-eight hours after onset died from pulmonary embolism, in 1952–54 only 1% died HONEY and TRUELOVE consider that their figures show that "anticoagulants do not have any major influence upon the course of an established myocardial infarct per se, although they save some lives by removing almost completely the dangerous complication of pulmonary embolism" These conclusions are indeed in striking contrast to those of IRVING WRIGHT and the American Heart Association's survey, and to those of GILCHRIST and his associates in Edinburgh IRVING WRIGHT has restated his opinion,[3] supported by many others, that "if a patient suffers from a definite myocardial infarction, if there are no contraindications and if good facilities are available, he should receive anticoagulant therapy" HONEY and TRUELOVE's answer to these claims is that the figures on which they are based have not been adequately analysed and, in particular, insufficient attention has been paid to bias in the selection of patients which has the effect of exaggerating good results—by this they mean the tendency to allot relatively poor risk patients to the "control" untreated groups They point out that bias in selection of this type can be shown to account for previous good results reported from their own hospital with the same patients in the period 1948–51

In their second paper HONEY and TRUELOVE assembled facts about the long-term prognosis, derived from their well-observed group They found that 1 patient in every 10 admitted died within forty-eight hours, and one-third of the patients were dead by the end of the eighth week, after two years had elapsed half the original patients were dead Thereafter the risk of dying diminishes, another 10% died in the next three years, and by the end of five years 3 out of 5 patients were dead Of the patients who survived the acute attack, 10% died during the succeeding four months, and factors of bad prognosis in this group were evidence of cardiac distress in the early period of the acute attack—i e , cardiac failure or enlargement, or the occurrence of arrhythmias—and a history of previous myocardial infarction When patients are classified as " bad risks " or " good risks " according to the criteria of Russek and Zohman, the bad-risk patients are four times as liable to die in the first year as the good risks, and twice as liable in the second year , but after the second year there is no difference Good-risk patients over the age of 60 have a better prognosis than younger patients, because younger patients are more liable to recurrence (Oddly enough, according to Morris et al ,[4] this does not apply to medical practitioners) Honey and Truelove point out that it is therefore very important to find out whether long-term anticoagulant treatment will reduce the recurrence-rate in these good-risk patients under 60 years of age , and their figures will provide a standard for comparison since only a very few of their patients had this form of treatment So far no comparably large series of cases is available for analysis Keyes et al [5] treated a group of 121 cases for varying periods up to thirty-eight months and considered that the mortality from recurrence was much reduced, but their figures are not very closely analysed They do warn physicians that stopping long-term anticoagulant treatment is very liable to be followed by a further acute myocardial infarction Schlachman [6] recorded 3 patients whose anticoagulant treatment was begun as soon as premonitory symptoms occurred, but it did not arrest the progress of the myocardial infarct Such findings warn us that long-term anticoagulant therapy is not to be lightly undertaken

[3] Wright I S *J Amer med Ass* 1957, 163, 918

Honey and Truelove's conclusions and criticism of previous workers' results are unlikely to pass unchallenged by the supporters of anticoagulant treatment for all But they are not alone in their views Russek and Zohman,[7] for example, have again expressed the opinion that " anticoagulant therapy, which has certain hazards, is neither necessary nor desirable for patients who have been classified as good risks " They give data about 511 good-risk patients who were not treated with anticoagulants , the patients were closely watched for thrombo embolic complications, which have occurred in only 19 (3 7%) of the cases and were always mild , only 18 (3 5%) deaths occurred in this group Russek and Zohman do, however, recommend anticoagulant treatment for poor-risk patients

The ordinary practitioner has therefore to come to a decision about individual cases in a field where experts continue to disagree He is likely to note that the opposing views are largely a matter of differing application of statistical methods of analysis to similar data But the arguments of Honey and Truelove and those who share their views will reinforce the physician's conviction, which must be communicated to anxious relatives, that not every patient with myocardial infarction needs admission to hospital , and Morgan Jones's [8] advice on the relative risks of transportation to hospital or no anticoagulants for the good-risk patient is still a good guide On the other hand, Honey and Truelove's statistics are unlikely, we think, to deflect hospital physicians from treating poor-risk patients with anticoagulants as soon as possible As Gilchrist and Tulloch [9] would doubtless remark, the saving of 11 lives in 263 patients is worth the effort

Annotations

AN EPIDEMIOLOGICAL STUDY OF MONGOLISM

In the past, the epidemiological approach to the causation of congenital malformations has been neglected It is probable that there are major variations in the incidence of malformations from country to country one instance is the high incidence of congenital dislocation of the hip in parts of Italy Some of these variations may depend on differences in gene frequencies, others on environmental differences , and these should be discoverable by epidemiological study

In an article on p 1314, Dr Pleydell (who has previously made a valuable study of Huntington's chorea in his county [10]) reports an epidemiological study in Northamptonshire of four types of malformation of unknown ætiology—mongolism, congenital malformations of the heart, hare-lip and cleft palate, and major malformations of the central nervous system He finds some apparently remarkable groupings in the births of children with these malformations, particularly mongolism, over the years 1944–55 Thus of 13 mongols born in the county of Northampton in 1947–48, no less than 5 were born in the Rushden area, whose population is less than a tenth of that of the county In evaluating apparent coincidences of this kind, it is important to discover whether they differ significantly from the random distribution Dr Pleydell does not give the details of his subdivision of the county, but two models will illustrate the possibilities of analysis

Let us suppose that the county is split into 100 regions, each with a population of about 3000 and about 50 births a year, and assume that the risk of any birth producing a mongol baby is 1 in 500 (Pleydell's figure of 1 in 613 agrees well with other surveys) Over a ten-year period of a total of 1000 region-years the number with no mongol births would be about 905, the number with 1 mongol birth about $90^1/_2$, with 2 about $4^1/_2$, and with 3 about $^1/_7$ That is to say, the odds would be only about 6 to 1 against any region having 3 mongol children born in a year Not less than 4 mongols born in one region, in one year of a ten year period, would be remarkable in populations grouped in this way In this light, that 3 mongols were born in nine months in Irthlingborough (population 4700) in 1947 is not by itself surprising Taking larger regions, with populations of about 30,000, and annual births about 500, the odds against 5 mongols being born in one year in such an area are only between 2 and 3 to 1, and only 7 or more in a year in a population of this size would be really noteworthy But these are exceptional individual events and an accumulation of discrepancies in different areas of the kind Dr Pleydell describes, each not significant in itself, might well be meaningful in combination

Now that Dr Pleydell has formulated the hypothesis that births of mongols are not random in time and space, we hope that it will be checked in one or two other counties There is no need for the population of the county to be subdivided into units of exactly equal size , but the subdivision should be fixed before the inquiry is made, and then the pattern of mongol births compared with what might be expected by chance

[10] Pleydell, M J *Brit med J* 1954, ii, 1121

A second suggestion of Dr Pleydell's is that there has been a seasonal incidence of the mongol births in his twelve year period of study, and that this may be related to the incidence of scarlet fever some seven or eight months previously This is an interesting hypothesis, but it needs confirmation since Pleydell's own findings as tabulated do not show a seasonal distribution greatly different from random expectation It is improbable that any short-lived infection in pregnancy could by itself be the cause of mongolism, even though the incidence of streptococcal infections varies with age For example, though (as Dr Pleydell notes) there are age specific differences in the incidence of streptococcal infection, it is difficult to explain in this way the fiftyfold increase in the incidence of mongolism from mothers aged 20 to mothers aged 45 But such environmental findings may play an important subsidiary rôle in mongolism, and even the main rôle in other malformations such as those of the heart

TESTOSTERONE THERAPY IN STUNTED CHILDREN

THOUGH testosterone is sometimes given to promote growth in stunted children, there are very few careful studies of its results The difficulty is largely one of knowing what growth would have taken place in the absence of the hormone, and, short of treating one of a pair of identical twins, no perfect control is possible The child's progress should be followed for six months to a year before any therapy is given, and thereafter with or without therapy for several years—if possible to full maturity A recent study by Sobel et al [1] goes a long way towards meeting this criterion, and considerably clarifies the main issue whether the immediate increase in height is ultimately outweighed by the earlier closure of the epiphyses also thought to be brought about by the hormone

Sobel et al studied 27 stunted children aged 5 to 10 years (thus avoiding the complications of the adolescent spurt in growth) They assessed their results by following on the one hand the increase in height, and on the other the increase in skeletal age—the latter being estimated in the usual way from radiographs of the hand and wrist. During six months before therapy, these children developed more slowly than was expected from the standards for Boston children, increasing by 4 7 months of average growth in height and by 4 3 months in skeletal age Testosterone was then given daily for six months, and there was a fairly sharp acceleration in height-growth and in skeletal maturation Height increased during these six months by the equivalent of 12 1 months of average growth, and reverted in the following year, without therapy, to the near average figure of 13 2 months of average growth Skeletal age increased 13 9 months during the six-month therapy period, and during the ensuing year continued to develop at above-average rate, advancing 17 0 months

Though it is usually believed that testosterone causes epiphyseal closure, the evidence for this is confused and contradictory, and indeed very little is known of the hormonal control of skeletal maturation—that is, of the "bone age"—in children [2] Under the abnormal stimulus of androgens in precocious puberty, the bone age is advanced, the epiphyses close early, and permanent stunting results Sobel et al now show that methyltestosterone 5 mg a day by mouth for six months accelerates bony development though without closing the epiphyses But in just over half the cases the acceleration in bony development was proportionally greater than the acceleration in height, and if therapy had been persisted in the effect would ultimately have been the reverse of what was desired Despite the immediate gain in height, the end-result would have been still greater stunting At present no effective preparation of growth-hormone is available, and while we wait for it, we should evidently avoid substitutes that do more harm than good

PROTECTION AGAINST RADIATION

ONE important way of minimising the dangers of ionising radiation is to ensure that everyone who works with machines or substances producing such radiation understands their power and adheres to rules known to be safe A new code of practice for the protection of radiation workers is published this week [1] Prepared by the standing advisory committee, under the chairmanship of Sir Charles Darwin, F R S, which was set up under the Radioactive Substances Act to advise Ministers, the code is intended primarily for the protection of persons exposed to ionising radiations in hospitals in the National Health Service

The code deals chiefly with technical data concerned in assessing the necessary safeguards to the users of X-ray and other radiological apparatus, such as cobalt therapy units, and radioactive isotopes It has been designed, as far as possible, as a set of purely technical rules The first part contains the rules applicable to the use of X rays in diagnosis and of X rays and γ rays in therapy, and the second part sets out rules for the diagnostic or therapeutic uses of radioactive isotopes, either sealed or unsealed A supplement records the relevant fundamental data and technical details about the design of diagnostic and therapy departments

Though the code makes no new scientific contribution, it incorporates much of the latest evidence, including the views of the Medical Research Council committee on the hazards of radiation, and it is a valuable working manual that will do much to fortify safety precautions The Minister of Health has sent copies to hospital authorities and has asked them to ensure that where necessary safety standards in radiological departments are brought into line with the code He emphasises that the clinical freedom of the individual consultant will not be restricted, but it has become essential, he adds, to secure a definite minimum standard of safety precautions and to place upon the head of the department the responsibility for maintaining that standard

POSTOPERATIVE SICKNESS

POSTOPERATIVE sickness is still one of the commonest complications of surgery and anæsthesia The principal predisposing factors are the use of opiates for premedication and postoperative analgesia, inhalational anæsthetic agents, and long major operations

The emetic effects of morphine are well known, but pethidine—though less troublesome in this respect—considerably increases postoperative sickness when given intravenously during an operation Burtles and Peckett [2] record an incidence of postoperative sickness of 18% after thiopentone, nitrous oxide, and oxygen, rising to 30% with the addition of intravenous pethidine, and an incidence of 26% with a similar anæsthetic sequence and trichlorethylene, rising to 46% with added pethidine All the potent inhalational anæsthetic agents are likely to produce some sickness, but ether remains the greatest offender amongst those commonly used

The site of surgery is probably of little importance (if operations on or near the labyrinth are excluded), and contrary to common belief intraperitoneal operations are no more likely than others to produce vomiting [3] But the incidence is high after protracted and major operations Women are more susceptible than men, and advancing years seem to lead to increasing resistance Other factors worth remembering are badly administered anæsthesia (which may result in severe anoxia or carbon-dioxide retention), idiosyncrasy (history of sickness after a previous operation or of travel sickness), and the emetic effect of anything more than occasional sips of fluid immediately after operation

[3] Knapp M R, Beecher H K *J Amer med Ass* 1956, 160, 376

Appreciating these and other ætiological features, the anæsthetist can vary his technique to suit the patient's requirements, but for general prevention and treatment the phenothiazine drugs offer the best prospect of success The value of these agents stems from their depressant effect on the region of the vomiting-centre, so that whatever the cause they are likely to work In susceptible patients they may not entirely prevent vomiting, but they usually reduce its severity Burtles and Peckett [3] found an overall sickness-rate of 30% in their control series, but this fell by half when a phenothiazine drug was given as part of the premedication They chose either promethazine or chlorpromazine, but ultimately they preferred the former, since with it such side effects as cerebral depression, dizziness, and postural hypotension were less troublesome Various workers have remarked on these side-effects of the phenothiazine drugs, and in certain circumstances it may be safer to accept the dis advantages of postoperative sickness than to add to the danger of the operation in this way In any event severe sickness is rare in Burtles and Peckett's series only 2 8% of patients vomited more than four times

BENIGN MYALGIC ENCEPHALOMYELITIS

LAST year we suggested the name " benign myalgic encephalomyelitis "[4] for an epidemic disease which is either new or has become very much more frequent than formerly It is a disease of rapid onset characterised by (1) symptoms and signs of damage to the brain or spinal cord (lower-motor-neurone palsies may lead to confusion with anterior poliomyelitis), (2) protracted muscle pain, (3) emotional disturbance, notably depression, extending into convalescence, (4) normal cerebrospinal fluid (C S F), although headache and stiff neck are common, (5) reticulo endothelial reaction in some cases, (6) a protracted course, often with relapses, and (7) a benign outcome in almost all cases

In London the Royal Free group of hospitals experienced a severe outbreak of a disease which apparently falls into this category, and its epidemiology has recently been described [5] The incubation period is usually 4–8 days, so an epidemic is likely to be explosive In this instance there were two fresh cases in the 3rd week of the epidemic, whereas in the 5th week there were fifty Although a few cases were found in which the disease was acquired from a single symptomless carrier, it was commonly transmitted by frequent personal contact, and in those circumstances the incidence of the disease was high Thus in the section of the hospital where the first case occurred 55% of the nurses contracted the disease within a month Since the largest number of cases was among nurses, the various types of worker in the hospital were roughly grouped according to the relative frequency with which each came into contact with members of the nursing staff, and the incidence of the disease in each group broadly corresponded with the frequency of contact The importance of frequent contact in the spread of the disease is also indicated by the low incidence of the disease outside the hospital when it was at its height among the hospital staff In contrast to the influence of frequent personal contact a search for a vehicle of infection—water, milk, food, laundry, insects—revealed no common links between cases There was no good evidence that age or sex affected liability to the disease, except in so far as these factors affected the probability of an individual being frequently exposed to infection Attempts were made to isolate the responsible virus at various stages of infection from nose, throat, blood, and bowel, but without success Serological tests were negative except that nearly 80% of those affected showed heterophil antibody in a titre of 1/40 or higher, but of these antibodies less than 4% were of infectious-mononucleosis type

This epidemiological study indicates that the risk of infection is greatest for anyone exposed to many infective persons, as in any form of community life, and that, on the contrary, in smaller units such as the home the risk of spread is slight At the Royal Free the epidemic was cut short by sending all the nurses home and keeping them under observation through their own family doctors, and no secondary case occurred as a result [6] Since the work of a large group of hospitals can be paralysed by an epidemic of benign myalgic encephalomyelitis, it is important to know of the success of this measure The management of an epidemic of benign encephalomyelitis is the reverse of that generally recommended for an epidemic of poliomyelitis in a closed community, such as a residential school, where sending all the children home is likely to disseminate the disease

SKIN GRAFTING BY THE EXPOSURE METHOD

SURGEONS often teach that skin is the best dressing, yet even with the high price of gauze and cotton wool today not all of them practise what they preach Sir John Bland-Sutton, it is said, thought that well-laundered sheets were the only cover needed by a healthy wound, and a return to this principle has lately been evident in the popularity of a pliable plastic film, sprayed on to the wound [7] The main value of the orthodox dressing is its absorbency, and the barrier to infection which it provides, and in freely draining wounds in which the risk of contamination is high because of their wetness there is still no better covering It is now recognised, on the other hand, that where the exudate is reasonably scanty, and contains (as it usually does) fluid protein, it will coagulate on the surface and provide an effective natural barrier Moreover this layer can easily be damaged by the pressure and movement of dressings, and fluid exudate, soaking into the gauze, may form an ideal medium for cross infecting organisms In the treatment of burns the exposure method is simple and often effective, and the progress of the burn can be observed and the moment chosen for surgical intervention in the doubtful case

In the more unfavourable situations split skin grafting is bedevilled by the risk of movement or pressure by the dressings displacing the newly adherent grafts, particularly where low grade infection (so difficult to eliminate from granulating surfaces) tends to cause the grafts to float off in their first few days Cannon [8] has found that with the exposure method split skin cover is feasible in many different circumstances—mobile areas such as the lower part of the abdominal wall, and the hand, moist wounds such as the granulating edges of a cerebrospinal fluid fistula, and lesions of the buttocks and thighs in paraplegic patients, and bony cavities once lined by granulation tissue This is just the kind of development which would have appealed to Ambroise Paré the replacement of an unsatisfactory ritual method by a simpler and apparently more effective one

The Wider World

REFLECTIONS ON MEDICAL TRAVEL

L J WITTS
D M Oxfd, M D Manc , Hon Sc D Dubl , F R C P
NUFFIELD PROFESSOR OF CLINICAL MEDICINE,
UNIVERSITY OF OXFORD

(concluded from p 1292)

One of the surprising things about the world is how little all the various modes of communication—talking, writing, photography, cinema, radio, and television—have prepared one for it Like psycho analysis, it must be experienced to be appreciated Who would have expected that one's auditory memory of San Francisco would have been the droning of fog-horns, of Bangkok the barking of dogs, and of Calcutta the cawing of crows ? Who would have supposed that Australian weather is even more unpredictable than British ? Who could have visualised, without seeing it, the squalor of the cities of the East, where the growth of population is exploding in an unpredictable chain reaction ? Who could have imagined the dinner of an Indian medical association, held in an enormous marquee like one of the tents of Genghis Khan, on a night so chilly after a summery day that the women all wore overcoats, and with the cold comfort of cocktails of lemonade and passion-fruit juice ? But, indeed, who could have imagined the miraculous beauty of India in the autumn, the light of the morning and the dust of the evening on the plains, the entrancing dress of the women, the colour that flames out of poverty ? Indian civilisation is as stable as the old red sandstone of its buildings, and out of it flowers an idealism like the airy cupolas and minarets that float above its forts and temples

* * *

Having known Australians and New Zealanders as a combative people, one of the surprises was to find them so amiable in their native land Indeed, Australians and New Zealanders differ from birds and dogs in being much more aggressive when they are abroad than when they are in their own territories They tell me we are the same At any rate, nothing can rival the friendliness and hospitality with which the Englishman is welcomed in Australia and New Zealand One is, of course, appalled by some aspects of the social scene in Australia—the evening swill of drink, the gambling, the lotteries, and the social strife One sometimes gets the impression that the aim of the Australian trades unions is to stop people working, and the aim of the Churches is to stop people enjoying themselves , but who are we to talk, with shipbuilders, engineers, railwaymen, and doctors behaving as they are ? With all its faults, however, Australian democracy is more real than any I have experienced elsewhere, and it is not overshadowed by plutocracy as it is in the United States of America The Australian taxi-driver is just as delightful and helpful as the Spanish, and that is saying a great deal You sit alongside him in the Holden cab and talk like two equals, and you learn a great deal about the country in the process He may, indeed, give you a good tip for the races you are just going to, and you may find that his brother owns a racehorse

Australian medicine is the apotheosis of private practice, extreme efficiency in the practical aspects of medicine being combined with a deficiency in that academic framework of the teaching hospitals which has made German medicine in the past and American medicine in our own time so great This is being remedied by the creation of new professional units, but the struggle will be an uphill one Australian thought at any rate in the professions, is intensely hostile to control by the State, and whole-time medicine is suspected of being a Trojan horse The various medical insurance schemes which have been introduced encourage the independence of the practitioner and the maintenance of private practice, but they probably do not promote the most efficient development and use of medical services, hospitals, and university clinical departments It is much more difficult to run a diabetic clinic or a hæmophilia reference centre in Australia than in this country, because the combined cost of transport to the hospital and treatment there is so much higher than the cost of treatment by the local practitioner

I am not persuaded that all Australian doctors should be trained in operative gynæcology, obstetrics and surgery A man in a group practice of 6000 cannot be a first-class surgeon, and so long as such a high proportion of the population lives in five of the State capitals where excellent hospital facilities are available, one would deprecate amateur surgery A great deal of the emphasis on the necessity for the general practitioner to be able to do surgery and major obstetrics seems to spring from the desire to give the practitioner an interesting and lucrative career rather than from the desire to give the cheapest and best service to the public Anyone who challenges a cherished national concept like that of the Australian doctor, located in the outback, hundreds of miles from help, self-sufficient and omnicompetent, is likely to provoke a violent reaction , but the gearing of the whole organisation of medicine to this uncommon person may not now be for the best A follow-up of the careers of a representative sample of Australian students qualified since the war would be of great value. Just as production changes—first subsistence agriculture, then a smaller and smaller proportion of the population as primary producers (in Australia not more than one in ten)—so medical practice changes , and in England now only 40% of those graduating go into general practice, the others being absorbed in diagnostic services, consultative work, preventive medicine, and similar specialised activities

* * *

An aspect of Australian democracy that is surprising to the Englishman, who has perhaps forgotten how many Australian families were driven there by the harsh penal laws of Great Britain and how many were kept in virtual slavery to British administrators, merchants, and landowners when they arrived, is that her Asiatic neighbours are prepared to regard Australia as a liberated colony and an anti-colonial power In addition, they do not fear her economic and military might as they fear that of America, China, and Russia Hence, they turn to Australia for advice and technical assistance A Scotsman, now professor of medicine in an Australian university, spoke movingly of the chagrin he had felt on a mission to Indonesia, in which for the first time in his life he had had to conceal the fact that he was a Scotsman Australia is taking an active part in the Colombo Plan, and on visiting the classrooms and libraries in the universities one is surprised by the high proportion of Asiatics among the students and readers Indeed, Australia is putting us to shame by the contribution she is making to education and scientific developments in Asia and Melanesia, and is illustrating the new pattern of empire in which we should be taking a greater part

* * *

On passing from Australia to the Far East, one feels as if one had moved back in time to Edinburgh or Dublin of fifty years ago, except that the classes are much larger There is excessive emphasis on anatomy and pharmacognosy, because these subjects are easy to teach with primitive facilities There is a great shortage of modern apparatus for physiology, biochemistry and clinical pathology, and an equal shortage of teachers and technical staff The teachers themselves are well aware

help from wealthy Catholic relatives because he was an agnostic.

Two wars and conscription have blunted our appetite for the *Wanderjahre* and we have organised a national health service that makes no provision for the prodigal's return. We do not make experience in Africa or Asia a *sine qua non* for a consultant appointment, as the Belgians and the Dutch used to do. Instead, the senior medical registrar casts a lean and hungry look at the 20 openings a year for more than 200 of his kind, and fears with justification that if he gets off the local ladder of promotion, even for a year or two, he will never get on again. No longer can the man who has spent twenty or thirty years working in the tropical sun return home and buy a comfortable small practice with opportunities for hunting and fishing. In too much of our planning since the war we have been parochially minded.

Conclusion

The reward of travel is to see one's own country in perspective, and my main impression is of the central position we occupy in the thoughts of diverse peoples, and of our responsibility to continue to help in the control of disease and the training of doctors in our former dominions now that we have been divested of the material trappings of empire. More than once I have seen again in my own daydreams the man who appeared in a vision to St. Paul saying, "Come over into Macedonia, and help us."

A second impression is of the great and lasting effect that may be produced on visitors to this country by some brief encounter which we too quickly forget. Listening to votes of thanks ten thousand miles away from home, I have learnt for the first time how much it means to a man to come to this country, to find that there are people who are bubbling over with enthusiasm about some small field of specialisation or research over which he himself had hitherto felt a little self-conscious, or, unfortunately, to meet someone like Martha who is too busy with the daily chores to put work aside and talk to the stranger.

If one writes freely, as I have tried to do, it is hard to avoid saying things which may be misinterpreted or may unintentionally hurt, and I must therefore stress my final impression, which is of the open-hearted friendship and bountiful hospitality which the English visitor receives abroad and the sense of obligation with which he returns. Nor should I like to close without praising the British Council, whose merits are so much better appreciated abroad than at home and whose advice and hospitality are so generously offered to the traveller from this country.

Medicine and the Law

Insulin Coma in a Driver

A DIABETIC patient was found by a policeman in his invalid carriage at the entrance to his garage.[1] He had had hospital treatment. He told police that if he had felt a turn coming on he would have taken a lump of sugar which he always carried with him.

He was accused of being in charge of a motorised invalid-carriage while under the influence of a drug. The prosecution said that he had taken a dose of insulin that had made him go into coma. A physician, referring to the patient's lump of sugar, said: "It is in that way that most of our diabetics keep out of court."

The patient was found guilty, but given an absolute discharge. The defence considered it "a vital case from the point of view of diabetics who drive."

MEDICAL RESEARCH COUNCIL'S STATEMENT ON TOBACCO SMOKING AND CANCER OF THE LUNG

THE following statement has been issued by the Medical Research Council.

THE INCREASE IN LUNG CANCER

In their annual report for 1948–50 the Council drew attention to the very great increase that had taken place in the death-rate from lung cancer over the previous twenty-five years. Since that time the death-rate has continued to rise, and in 1955 it reached a level more than double that recorded only ten years earlier (388 deaths per million of the population in 1955 compared with 188 in 1945). Among males the disease is now responsible for approximately 1 in 18 of all deaths. Although the death-rate for females is still comparatively low, it also has shown a considerable increase in recent years and the disease is now responsible for 1 in 103 of all female deaths.

Three comments may be made on these figures. In the first place, the trend over the last few years indicates that the incidence has not yet reached its peak. Secondly, the figures are not to be explained as a mere reflection of the introduction and increasing use of improved methods of diagnosis but must be accepted as representing, in the main, a real rise in the incidence of the disease, to an extent which has occurred with no other form of cancer. Thirdly, only a small part of the rise can be attributed to the larger numbers of older persons now living in the population; in the last ten years the lung-cancer death-rates among both men and women have risen at all ages from early middle-life onwards.

POSSIBLE CAUSES OF THE INCREASE

The extent and rapidity of the increase in lung cancer point clearly to some potent environmental influence which has become prevalent in the past half century and to which different countries, and presumably also men as compared with women, have been unequally exposed. The pattern of incidence of the disease rules out any possibility that the increase can be due, in a substantial degree, to special conditions, such as occupational hazards, affecting only limited groups. It is necessary to seek some factor or factors distributed generally throughout the population, and in considering the possibilities it must be borne in mind that a very long period, 20 years or more, may elapse between exposure to a carcinogenic agent and the production of a tumour. From the nature of the disease attention has focused on two main environmental factors: (1) the smoking of tobacco, and (2) atmospheric pollution—whether from homes, factories, or the internal combustion engine.

SMOKING AS A CAUSE OF LUNG CANCER

Epidemiological Surveys

The evidence that heavy and prolonged smoking of tobacco, particularly in the form of cigarettes, is associated with an increased risk of lung cancer is not based on the observation that the substantial increase in the national mortality followed an increase in the national consumption of cigarettes. It is derived from two types of special inquiry. In the first, patients with lung cancer have been interviewed and their *previous* histories in relation to smoking and other factors that might be relevant have been compared with those similarly obtained from patients without lung cancer. The results of nineteen such inquiries (in this country, the U.S.A., Finland, Germany, Holland, Norway, and Switzerland) have been published. They agree in showing more of these defects. At the clinical level there are great deficiencies in social and preventive medicine, pædiatrics, and psychiatry.[2] By social medicine is meant not the detailed case taking—in many respects the modern equivalent of slumming—which is so dear to the hearts of British almoners and which has made the subject so distasteful to the average British medical student. It means public health, the medicine of communities, and in particular the medicine of communities in which the income per head and the proportion of doctors to patients are very small.

---

[1] *Times*, June 21.

This is not to say that there are not institutes in the Far East and particularly in India which can compare with the best in Europe and America. New hospitals are being built and American aid is being poured in. The Americans are readier or better able than we to use the device of adoption of a school overseas by one in the United States and to arrange an interflow of staff—of trainees to the United States and of senior American staff and technicians to Asia. English is the key language to the world's scientific literature, and in view of the costs and delays of translation it is unlikely to be replaced by languages such as Hindi or Arabic as a medium of scientific instruction. So long as English remains the lingua franca of medical teaching, exchanges are essential, for there is a tendency for spoken English in India to diverge from the language spoken in England and America as spoken Latin diverged in Italy and Spain. The gain of these exchanges is not all on one side. There are great opportunities for research in Asia, whether in old fields such as the treatment of tuberculosis or in new ones such as the abnormal hæmoglobins.

It is all too easy to sneer at the efforts of the Asian and African students who come to this country to take a higher qualification in medicine or surgery, to lament that their previous training is defective and to assert that the Asian student may learn theory with the greatest of ease but is no good at getting to grips with the real world. Doubtless the social background in the East, with its enormous labour surplus, makes men and women used to being waited on hand and foot; but it does not prevent the development of doctors and nurses of great practical competence. Indeed, the Pakistani girl who has come direct from purdah to become a doctor or nurse has made a much greater step forward than the British student of medicine or nursing.

* * *

The desire for British or American higher qualifications is a good aspect of the nationalism which dominates world thought today. Just as every country must have air-lines, air hostesses, air fields, radio, and if possible television, of international standards, so too its medical teachers must be of international status. Moreover, only an external criterion of ability can prevent the nepotism which is still such a danger. It is for these reasons that in much of Asia today it is almost impossible for a man to get on the staff of a teaching hospital without having studied abroad and obtained a British or American higher degree.

This is almost certainly a temporary phase. When the peoples of Asia and Africa become more assured, they will probably no more think of coming here to take the M.R.C.P. or the F.R.C.S. than an American or European postgraduate student does today. While the phase lasts, however, we should bend every effort to help. Wherever one goes in medical circles in India and the Far East, the conversation soon turns to the difficulties which face their young men and women in getting house appointments in this country (even though they are sponsored by their universities), the difficulties of temporary registration, and the difficulties of satisfying the preliminary conditions for sitting examinations such as the membership of the College of Physicians. It is freely stated that we make much greater difficulties than the Americans. There is a desire for English external examiners, inspectors, and postgraduate lecturers who will make the preparation for higher degrees more efficient.

* * *

I have said this is a temporary phase, because by and large Western medicine provides an unsuitable training for the problems of the East. They need an autochthonous form of medical education. Experiments on new lines have already been carried out at Vellore and Ludhiana, where medical education is oriented to public health and it is as important for the student to work at the rural health centre as to walk the wards of the hospital. The most important experiment is the All India Institute of Medical Sciences, which is being built at Delhi to be the Indian Johns Hopkins Hospital and train the teachers and researchers of the future. The number of students will be small and they will be selected from the whole of India. Faculties and staff will be provided on a relatively lavish scale.

It is doubtful whether at the start India will be able to staff this institute unaided and she will probably be anxious for help from England and America. Such help will have to be on a short-term basis, because India will naturally want the project to be firmly in Indian hands. The seconding of an English medical teacher to work for, say, two years in Delhi bristles with difficulties because heads of departments cannot easily be away so long and younger men fear the loss of promotion during an absence. In addition, living expenses may well be high. However, the compensations would be great. In the ordinary way I share Sir Robert Hutchison's view of "that most boring of subjects, the medical curriculum", but working out a medical curriculum for India could be exciting, for in India and the Far East people must sit down and think out from the beginning what they are training doctors for and the best way of doing it.

The visitor to India cannot but marvel at the outburst of creative energy liberated by independence, the enthusiasm for planning and the immensity of the tasks to be completed. At the top levels of their health service there has been a fusion of the best elements of the traditions of the Indian Medical Service, the Indian Civil Service, and the Congress Party into a precept of idealism and dedication to duty which fills the sympathetic visitor with respect. Like Wordsworth witnessing the French revolution, he murmurs, "Bliss was it in that dawn to be alive." Friendship to Britain is sincere, and it is surprising how tolerantly the relics of our domination have been preserved, for some of the manifestations of the Victoria cult were as inartistic as those of the Stalin cult. Pakistan is a smaller and poorer country than India, but friendship to Britain is as strong there or stronger and the desire for our cooperation in education and the advancement of science equally great.

* * *

When I was a boy at the local grammar school, an old friend of my mother's used to say, "Put the lad in the Borough Treasurer's office and then he'll be right for life." The institution of the Welfare State has unfortunately set the seal of approval on the philosophy of being right for life and has weighted the odds against adventure. It is only necessary to read the autobiographical writings of Conan Doyle to realise how much harder were the conditions young doctors without means had to face two or three generations ago. Conan Doyle spent seven months on a whaling-ship in his final year to get the money to qualify. After qualification he had to go to sea again as ship's surgeon on the *Mayumba*, and on his return he complained of having had African fever, of having nearly been eaten by a shark, and of his ship catching fire in mid ocean. Despite his penury he refused help from wealthy Catholic relatives because he was an agnostic.

MEDICAL RESEARCH COUNCIL'S STATEMENT ON TOBACCO SMOKING AND CANCER OF THE LUNG

THE following statement has been issued by the Medical Research Council:

THE INCREASE IN LUNG CANCER

In their annual report for 1948–50 the Council drew attention to the very great increase that had taken place in the death rate from lung cancer over the previous twenty-five years. Since that time the death-rate has continued to rise, and in 1955 it reached a level more than double that recorded only ten years earlier (388 deaths per million of the population in 1955 compared with 188 in 1945). Among males the disease is now responsible for approximately 1 in 18 of all deaths. Although the death-rate for females is still comparatively low, it also has shown a considerable increase in recent years and the disease is now responsible for 1 in 103 of all female deaths.

Three comments may be made on these figures. In the first place, the trend over the last few years indicates that the incidence has not yet reached its peak. Secondly, the figures are not to be explained as a mere reflection of the introduction and increasing use of improved methods of diagnosis but must be accepted as representing, in the main, a real rise in the incidence of the disease, to an extent which has occurred with no other form of cancer. Thirdly, only a small part of the rise can be attributed to the larger numbers of older persons now living in the population; in the last ten years the lung-cancer death rates among both men and women have risen at all ages from early middle-life onwards.

POSSIBLE CAUSES OF THE INCREASE

The extent and rapidity of the increase in lung cancer point clearly to some potent environmental influence which has become prevalent in the past half-century and to which different countries, and presumably also men as compared with women, have been unequally exposed. The pattern of incidence of the disease rules out any possibility that the increase can be due, in a substantial degree, to special conditions, such as occupational hazards, affecting only limited groups. It is necessary to seek some factor or factors distributed generally throughout the population, and in considering the possibilities it must be borne in mind that a very long period, 20 years or more, may elapse between exposure to a carcinogenic agent and the production of a tumour. From the nature of the disease attention has focused on two main environmental factors: (1) the smoking of tobacco, and (2) atmospheric pollution—whether from homes, factories, or the internal combustion engine.

SMOKING AS A CAUSE OF LUNG CANCER

Epidemiological Surveys

The evidence that heavy and prolonged smoking of tobacco, particularly in the form of cigarettes, is associated with an increased risk of lung cancer is not based on the observation that the substantial increase in the national mortality followed an increase in the national consumption of cigarettes. It is derived from two types of special inquiry. In the first, patients with lung cancer have been interviewed and their *previous* histories in relation to smoking and other factors that might be relevant have been compared with those similarly obtained from patients without lung cancer. The results of nineteen such inquiries (in this country, the U.S.A., Finland, Germany, Holland, Norway, and Switzerland) have been published. They agree in showing more smokers and fewer non-smokers among the patients with lung cancer, and a steadily rising mortality as the amount of smoking increases. In the second type of inquiry, information has been obtained about the smoking habits of each member of a defined group in the population and the causes of the deaths occurring *subsequently* in the group have been ascertained. There have been two such investigations, one in the U.S.A. covering 190,000 men aged 50–69, and the other in this country covering over 40,000 men and women whose names appeared on the Medical Register of 1951. In both, the results have been essentially the same. The investigation in this country, which has now been in progress for more than five years, has shown with regard to lung cancer in men:

(1) A higher mortality in smokers than in non-smokers.

(2) A higher mortality in heavy smokers than in light smokers.

(3) A higher mortality in cigarette smokers than in pipe smokers.

(4) A higher mortality in those who continued to smoke than in those who gave it up.

It follows that the highest mortalities were found among men who were continuing to smoke cigarettes, heavy smokers in this group having a death-rate nearly 40 times the rate among non-smokers. Although no precise calculation can be made of the proportion of life-long heavy cigarette smokers who will die of lung cancer, the evidence suggests that, at current death-rates, it is likely to be of the order of 1 in 8, whereas the corresponding figure for non-smokers would be of the order of 1 in 300. The observation on the effect of giving up smoking is particularly important, since it indicates that men who cease to smoke, even in their early forties, may reduce their likelihood of developing the disease by at least one half.

It should be noted that the excess of deaths from lung cancer among smokers was not compensated for by any corresponding reduction in the number of deaths from cancer of other sites in the body; in other words, there was a total incidence of cancer in the smoking groups in excess of the incidence that would have prevailed in the absence of smoking.

It will be apparent from what has been said that the evidence from the many inquiries in the past eight years, both in this country and abroad, has been uniformly in one direction and is now very considerable. It has been further strengthened recently by the observation from several sources that the extent of the relationship with smoking differs for different types of lung tumour which can be distinguished only by microscopic examination.

Laboratory Evidence

From the physical and chemical point of view there is nothing inherently improbable in a connection between smoking and lung cancer. Tobacco smoke consists largely of microscopic oily droplets held in suspension in air, and these droplets are of a suitable size to be taken into the lungs and retained there. Over a hundred constituents have so far been identified and, among these, five substances have already been found which are known to be capable, in certain circumstances, of causing cancer in animals. Some workers have succeeded in producing tumours in animals by painting concentrated extracts of tobacco tar on the skin. Known carcinogens are present in tobacco smoke in very small amounts however, and there is no certainty that such low concentrations could be harmful to human beings. Nevertheless, the finding of carcinogenic agents in tobacco smoke is an important step forward, in that it provides a rational basis for the hypothesis of causation.

ATMOSPHERIC POLLUTION AS A CAUSE OF LUNG CANCER

It has been known for some years that mortality from lung cancer is greater in urban areas than in the countryside. This fact, together with the identification of carcinogenic substances in coal smoke and in motor-vehicle exhausts, has led to the supposition that exposure to atmospheric pollution may be concerned with the increase in lung cancer. The rôle of atmospheric pollution is particularly difficult to investigate however, and the evidence is neither so consistent nor so extensive as that relating to tobacco smoking. On the one hand, no excess mortality from lung cancer has been observed in persons who would be especially exposed by the nature of their work to atmospheric pollution—for example, transport workers, garage hands, and policemen. On the other hand, the results of a number of investigations have suggested that a relationship does exist between atmospheric pollution and lung cancer. Perhaps the best evidence for this relationship comes from studies of the small number of deaths from the disease among *non-smokers in different types of residential district*; in these studies higher death-rates have been observed among non-smokers in large towns than among those in rural areas. On balance it seems likely that atmospheric pollution plays some part in causing the disease, but a relatively minor one in comparison with cigarette smoking.

ASSESSMENT OF THE EVIDENCE RELATING TO SMOKING AND LUNG CANCER

Knowledge of the causation of lung cancer is still incomplete. Many factors other than tobacco smoking are undoubtedly capable of producing the disease; for example, at least five industrial causes have been recognised. Nevertheless, the evidence for an association between lung cancer and tobacco smoking has been steadily mounting throughout the past eight years and it is significant that, during the whole of this period, the most critical examination has failed to invalidate the main conclusions drawn from it. It has indeed been suggested that the fundamental cause may be some common factor underlying both the tendency to tobacco smoking and to the development of lung cancer some twenty-five to fifty years later, but no evidence has been produced in support of this hypothesis.

In scientific work, as in the practical affairs of everyday life, conclusions have often to be founded on the most reasonable and probable explanation of the observed facts and, so far, no adequate explanation for the large increase in the incidence of lung cancer has been advanced save that cigarette smoking is indeed the principal factor in the causation of the disease. The epidemiological evidence is now extensive and very detailed, and it follows a classical pattern upon which many advances in preventive medicine have been made in the past. It is clearly impossible to add to the evidence by means of an experiment in man. The council are, however, supporting a substantial amount of laboratory research which may throw more light on the mechanism by which tobacco smoke and other suspected causative factors exert their effect, and which may thus eventually add to the degree of proof already attained as a result of studies of human populations. It must be emphasised, however, that negative results from work with animals cannot invalidate conclusions drawn from observations on man.

CONCLUSIONS

1. A very great increase has occurred during the past twenty-five years in the death-rate from lung cancer in Great Britain and other countries.

2. A relatively small number of the total cases can be attributed to specific industrial hazards.

3. A proportion of cases, the exact extent of which cannot yet be defined, may be due to atmospheric pollution.

4. Evidence from many investigations in different countries indicates that a major part of the increase is

associated with tobacco smoking, particularly in the form of cigarettes In the opinion of the Council, the most reasonable interpretation of this evidence is that the relationship is one of direct cause and effect

5 The identification of several carcinogenic substances in tobacco smoke provides a rational basis for such a causal relationship

REPORT ON MEDICAL RESEARCH

LUNG cancer, radiation hazards, vaccination against poliomyelitis, and genetics are among the chief topics of the Medical Research Council's latest report[1]

The Council's activities complement those of hospitals and universities, and the Council provides for clinical research only when its scale, scope, or urgency dictates Besides setting up its own permanent units, whose staffs have careers in research, the Council makes whole-time or part time appointments to its external scientific staff, grants to independent workers, and awards for training in research Moreover, it organises cooperative studies At the national level, the Council allocates funds for the support of clinical research in both major schemes and individual projects Decentralised research may be supported by regional hospital boards and boards of governors of teaching hospitals, here the Clinical Research Board can often give advice

As before, the report includes an excellent succinct account of trends in selected fields of medical research The many publications of the Council and its staff are then listed They include the report on the *Hazards to Man of Nuclear and Allied Radiations*,[2] presented to Parliament as a white paper

Overseas liaison continues by means of units in Gambia, Jamaica, and Uganda Research groups have been set up to study ageing, atmospheric pollution, inherited disease, and other topics, and units are being established to study (among other things) metabolic disturbances in surgery, carcinogens, and the effects of radiation

Special attention is paid to *lung cancer* on account of its striking increase in late years, it is the cause of 1 in every 9 deaths in middle-aged men Retrospective and prospective investigations all indicate a relationship between heavy smoking, especially of cigarettes, and most forms of lung cancer, and no investigation suggests absence of such a relationship Carcinogens have been found in cigarette smoke, these induce hyperplasia in human fœtal lung grown in tissue culture Industrial hazards (e g, from chrome and asbestos) and atmospheric pollution probably account for a small proportion of the cases Statistical surveys and laboratory experiments are continuing

Poliomyelitis vaccination in North America is by killed viruses of the Mahoney strain For the British vaccine a less virulent (Brunenders) strain was chosen, but the rhesus monkey used for safety testing was found to be insensitive to this strain A cynomolgus monkey (treated with cortisone, or cortisone and irradiation) is used Antibody studies in children have shown that the British vaccine produces titres (against all three types of virus) which compare favourably with those found after use of the American vaccine Experiments in monkeys show that the vaccine confers a high degree of immunity to artificial infection with a virulent strain In children aged $1^1/_2$–$9^1/_2$, after vaccination the attack rate of paralytic poliomyelitis in the 1956–57 season was a fifth of that in unvaccinated children Live attenuated poliomyelitis vaccines are being tried so far they have been trouble-free, but the antibody response has not always been satisfactory

In experimental *filarial infections* it was found that microfilariæ remained in the lung capillaries during the day, and were more generally distributed in the circulating blood at night The antifilarial drug diethylcarbamazine ('Banocide') acts similarly to an opsonin, and is effective in the blood stream but less so in places inaccessible to the phagocytes The drug is most useful in the mass treatment of communities Species of wuchereria similar to the human type have been found in animals, and several species of mosquito are now known to be involved as vectors The response of onchocerciasis to chemotherapy is not satisfactory, but control of the simulium fly vector by dicophane (D D T) has been successful

The importance of the *kidney* in regulating the water and electrolyte content of the body is agreed, but attempts to compare the efficiency of the kidney in adults and in children have been frustrated by lack of an agreed basis for comparison—the body-weight, body-surface area, and body-water content give differing results But by most criteria the kidneys of infants (human and rat) are less efficient than those of adults Happily a balanced diet and the requirements of growth (which dictate that little protein be broken down) ensure that, normally, not too much material is presented for excretion

Investigation of the nature of the difference between *normal and sickle-cell hæmoglobins* has shown that the only chemical difference lies in one peptide, which bears a positive charge in sickle cell hæmoglobin at pH 6 4 but is unchanged in normal hæmoglobin, this difference is due to the presence of a valine molecule in the charged peptide and a glutamic acid molecule in the neutral peptide This is the first time that the effects of a single mutation on the chemical structure of a protein have been elucidated When the sickle-cell-hæmoglobin molecules lose oxygen they may form fibrillar aggregates which attract one another into a parallel orientation, distorting the cell In homozygotes the illness is severe, and four-fifths of them die before reaching reproductive age, the persistent high incidence of sickling in some African tribes is thought to be due to the high resistance of heterozygotes to malignant tertian malaria, which largely compensates for the lethality of sickling In malaria-free regions (e g, the United States) the prevalence of sickle cell trait has fallen, as would be expected Heterozygotes carrying a thalassæmic factor may be similarly resistant to malaria Mutations of the kind, where genes are beneficial in one situation and harmful in another, are important in evolution

Microbial genetics is briefly discussed There are 3 mechanisms for the transfer of bacterial genes from cell to cell

(1) Transformation operates in, e g, pneumococci If deoxyribonucleic acid (D N A) is extracted from one strain and added to another, the recipient strain takes on some characteristics of the donor

(2) Transduction operates in, e g, salmonella When virus multiplies in a donor cell, some chromosome fragments become incorporated in the virus, and may be integrated into the chromosomes of new infected cells which survive

(3) Conjugation operates in, e g, the colon bacillus During temporary fusion of two cells, chromosome material passes from one to the other

A bacterial virus acts by attaching itself to the bacterial cell and injecting its D N A, which then takes control of the host's synthesising mechanisms, causing them to produce more virus D N A and protein Often bacteria become permanently infected ("lysogenic") with a phage virus, and able to transmit it to their progeny Some bacterial properties (e g, toxin production by diphtheria bacilli) are impossible except by lysogenic organisms

Homografts are normally destroyed (except for blood, whose cells have no nuclei, and cornea, which has no blood-supply). This does not apply to grafts between identical twins or members of an inbred strain, and the power to destroy grafts may be lost after irradiation. Irradiated mice, which would have been expected to die after a week or two, recover when inoculated with marrow. It has been shown that the homologous marrow actually colonises the irradiated host. Even grafts from another species (rat) may survive. Leukæmic mice have been successfully treated by irradiation heavy enough to destroy all the blood-forming tissue, followed by a marrow graft from a normal animal. Another means of making homografting possible is to inject tissue from another animal before birth; after reaching maturity the recipient will tolerate further grafts from the donor.

---

[1] Report of the Medical Research Council for the year 1955–56 H M Stationery Office Pp 247 9s

[2] See *Lancet* 1956 i 949

Other articles deal with the relationship between radiation and leukæmia, whooping-cough vaccines, protein turnover in tissues, the chemistry of proteins and peptides and of antibiotics, and mass spectrometry in gas analysis. The summary of work indicates the vast range of the council's activities—from hypogammaglobulinæmia to possible carcinogenic action of detergents. The list of publications is as long and impressive as ever.

Before Our Time

TOBACCO FASHIONS

WHEN the natives of North America discovered the Europeans in the 15th century they introduced them to the pleasures of tobacco—snuffed, chewed, and smoked. The form in which it was used in their society was probably governed to some extent by custom and fashion; and pipe smoking certainly had some religious and symbolic meanings. The history of tobacco-taking in Europe has also been strongly influenced by fashion, which, although partly shaped by authority, propaganda, and economics, owes much more to individual desires for novelty, distinction, emulation, and uniformity.

In England pipe smoking became the fashion of the rich in the late 16th century, and, as the price of tobacco fell, the habit spread to all classes, both sexes, and almost all ages; by the turn of the century it was a national pastime. On the Continent, on the other hand, the fashion was for snuffing. There was, of course, much opposition to all forms of tobacco using; and the first important book against it—the opinions of sundry learned physicians—was published as early as 1598. Two Papal Bulls proclaimed excommunication for being found guilty of using tobacco in the churches of Seville and within the walls of St Peter's in Rome. The Greek Church forbade its use entirely; and in Turkey, Persia, and India the death penalty was prescribed. A Russian tsar decreed that for the first offence the culprit should be whipped and for the second executed, while snuff-takers were to have their noses cut off; and Louis XIII of France prohibited its use unless ordered by a physician. In England, James I imposed a heavy import tax in 1604 and published his renowned Counterblaste with its bitter invective against the habit. But the fashion grew. Then, in the early years of the 18th century, it changed rapidly and there appears to have been no organised propaganda, legislation, or economic circumstance to account for this. In the time of the Stuarts, according to Sir William Besant, "the use of tobacco penetrated all ranks and classes of society. The grave divine, the soldier, the lawyer, the gallant about town, the merchant, the craftsman, the 'prentice, all used pipes. . . . People went to bed with tobacco box and pipe and candle on a table by the bedside . . . it is even stated that the very children in school took a pipe of tobacco instead of breakfast." But by the end of Queen Anne's reign the pipe had been deposed and the English were well set for a century of snuff taking.

Snuffing was already popular among all classes in France and in Scotland and Ireland. It seems probable that in England it grew up slowly among the "young bloods" as a protest against the excess to which smoking had been carried by the "lower orders." They imported the habit and the elegant ritual of snuff taking from the fashionable French with the fastidious attention to blend and perfume, the exquisite snuff-boxes, the tap on the lid and the delicate lifting of the pinch to the nose, the inaudible inhalation and elaborate gestures of the hands and dainty handkerchiefs. These affections, of course, were scorned by men such as Samuel Johnson who carried their snuff loose in their waistcoat pockets; but schools of etiquette gave instruction, as an advertisement of 1711 states, in "the exercise of the Snuff-box, according to the most fashionable Airs and Notions . . . with the best plain and scented snuff." An accident of war may have contributed to the rapid spread of the habit. In 1702 50 tons of fine Havana snuff captured in Spanish ships were distributed among the English seamen as perquisites. They sold it cheaply in England and flooded the market in the southern counties with excellent snuff at 3*d* or 4*d* a pound. By 1720 a contemporary writer was able to say: "The world has taken up a ridiculous fashion—the excessive use of snuff. All nations are snuffing. All classes snuff, from the highest to the lowest. . . . Both sexes snuff, for the fashion has spread to women; the ladies began it and it is now imitated by the washerwomen." Dr Johnson, fifty years later, remarked that "smoking has gone out. To be sure, it is a shocking thing, blowing smoke out of our mouths into other people's mouths, eyes and noses . . . yet I cannot account why a thing that requires so little exertion, and yet preserves the mind from total vacuity, should have gone out." According to Swift, the makers of snuff employed "by far the greatest number of hands of any manufacture of the kingdom." A snuff house was opened in the Haymarket in 1720 that has continued to blend and sell snuff without interruption to the present day. The ledgers and records provide an interesting history of fashions in the use of tobacco over more than 200 years. Queen Charlotte—nicknamed "snuffy Charlotte"—was a heavy snuff-taker and regular customer. Like many others she bought snuff by the pound, on Feb 20, 1804, ordering 12 lb of "Marrocca" at 8*s* 6*d* a pound with 4*s* for a "jar and bung" and another 6 lb on May 26. But by this time the craze of snuffing was waning. The mass of the people, among whom pipe smoking had never lost its appeal, were slowly discarding the snuff habit; and cigars were becoming more popular among the rich. Snuff remained highly fashionable in the foppish circles in which the craze had originated. Indeed, it reached a peak of fashionable excess in the time of the Prince Regent and Beau Brummell.

By the middle of the 19th century the famous Haymarket shop was supplying as many smokers as snuffers, and in 1859 a work on the habits of "grand society" recorded that the obsolete custom of snuffing was "retained only by a few old gentlemen." The birth of cigar smoking has been attributed to the Peninsular war, when the soldiers acquired a taste for Spanish cigars. The rise of cigarette smoking has been linked with the Crimean war and contact with the customs of the Turks and Russians. It may be significant that the snuff craze began about the time of the extended war of the Spanish succession on the Continent. But changes of fashion are not caused by single circumstances or events, though these may precipitate a change when the communal taste is ready for one. Both the sudden fashion of snuffing in the 18th century and the slower return to smoking in the 19th century followed periods when the habit had risen in quantity and quality to new heights of extravagance. It may be that the people were satiated with the monotony of one craze and ripe for the titillating novelty of another.

In the history of tobacco up to the appearance of cigarettes there is little evidence that the fashions were greatly influenced by the efforts of the tobacco trade. In the second half of the 19th century, however, tobacco advertising and intense competition for markets, together with increased production from the invention of the cigarette-making machine in 1880, undoubtedly influenced the fashion of smoking. In the past forty years the cigarette craze has blossomed as the pipe and the snuff crazes did before it. Changes of fashion can still happen without prompting: in the past ten years snuff sales in this country have been slowly but steadily rising without the aid of advertisement or preferential tax. The national fashion of ubiquitous cigarette-smoking may perhaps be reaching the limit of tolerable extravagance and be becoming ripe for decline.

Occasional Survey

SUBDURAL HÆMATOMA

THE first report on a traumatic subdural hæmatoma is probably that of Ambroise Paré[1]. He described the necropsy findings in King Henry II of France, who died in 1559 eleven days after being injured by a lance:

> "His skull being opened after his death there was a great deal of blood found between the dura and pia mater poured forth in the part opposite to the blow at the middle of the suture of the hind part of the head and there appeared signs by the native colour turned yellow that the substance of the brain was corrupted as much as one might cover with one's thumb."

Many reports of subdural accumulations of blood, or bloodstained fluid, were published in the following three centuries. In these a traumatic origin was usually assumed. But in 1857 Virchow[2] introduced the name "pachymeningitis hæmorrhagica interna." He emphasised the intradural origin of the chronic hæmatoma and its inflammatory character. Others (e.g., Huguenin[3]) postulated a traumatic origin for all hæmorrhagic effusions on the inner aspect of the dura mater. About the turn of the century Jores and his pupils[4–6] emphasised the need for examining membranes spread out flat, and sections of the dura cut in two directions at 90° and taken from various parts. They advocated that two conditions should be distinguished—i.e., traumatic subdural hæmatoma, and pachymeningitis hæmorrhagica interna (which might show either degenerative changes and vasoproliferation or fibrinous exudation and cellular infiltration). Aschoff[7] considered that the striking capillary proliferation, in the absence of fibrinous exudation, and cellular infiltration were not inflammatory in origin, and proposed the name "pachymeningosis hæmorrhagica interna." Changes in the collagenous fibres of the subdural membranes, the appearance of cystic spaces, the spread of fibroblastic proliferation, and vascular proliferation had been described by G. M. Robertson,[8] and by Ford Robertson,[9] who quoted Wilks and Sperling's finding of membrane formation after experimental injection of blood into the subdural space. Fahr[10] and Wohlwill[11] gave excellent accounts of the histological findings in pachymeningitis hæmorrhagica interna, and emphasised the capillary and endothelial proliferation in the absence of fibrinous exudate and without signs of organisation. The formation of wide engorged "giant capillaries" in the areolar layer of dura mater was generally recognised, particularly by Ostertag,[12] who studied the histology of pachymeningitis in whooping cough. Albertini[13] came to conclusions similar to those of Jores and Laurent.

In the United States, Putnam and Cushing[14] and Putnam and Putnam[15] claimed that the traumatic and the spontaneous forms showed histological differences. Baker[16] pointed out that the larger hæmorrhages took place in the inner capillary bed of the dura mater and dissected along the loose connective tissue of the submesothelial layer; he considered trauma an important cause but not the only one. But in general the unitarian traumatic theory was readily accepted, particularly when Gardner[17] and Putnam[18] put forward an attractive hypothesis to explain the symptomless interval and the gradual increase in size of a subdural hæmorrhagic cyst. Zollinger and Gross[19] supported the hypothesis by model-experiments. They assumed that the membrane enclosing a subdural hæmatoma is semipermeable and that the proteins which arise from the disintegrating erythrocytes exert a colloid osmotic pressure attracting fluids with low protein content, such as cerebrospinal fluid and possibly interstitial fluid of the dura mater. This is certainly a better explanation than repeated bleeding between laminated neomembranes, because, though the concentration of proteins in such a "blood cyst" is high, it is lower than that of blood, indicating a dilution with protein-free fluid[19]. The same pathogenesis was accepted for the pachymeningitis hæmorrhagica of infants, and the alternative name "chronic subdural hæmatoma" became popular[20–23]. Birth injury or insignificant, often overlooked, postnatal trauma were held to be the cause of the disorder.

Two thorough investigations on a very large material have lately been published. Link and Schleussing[24] studied the necropsy and histological findings from 941 patients aged over 16. They, like Gellerstedt,[25] separate sharply the traumatic subdural hæmatoma from true pachymeningitis hæmorrhagica. They believe that the fate of a post-traumatic hæmatoma depends on its size. Thus small hæmatomas are completely absorbed, leaving only hæmosiderotic pigmentation on the inner aspect of the dura mater; and larger ones result in rusty, brown, or brownish grey thin neomembranes or pseudomembranes (often erroneously called pachymeningitic membranes). The largest are organised like hæmatomas in any other part of the body, beginning with fibroblastic proliferation and capillary budding in the inner areolar layer of the dura mater, the end result is focal thickening of the dura mater—a dural scar In the intermediate stage, clefts sometimes appear, either naked or lined by fibroblasts which may resemble a mesothelial lining, but usually such clefts are the result of shrinkage or even post-mortem artefacts Wide spaces, when seen in spread-out membranes or sections parallel to the dural surface, communicate with each other, and cysts with one or many locules are exceptional Hæmosiderin-laden macrophages may be seen in any of the stages, and in the milder forms of subdural hæmatoma Extracellular hæmosiderin granules are rarer

In true pachymeningitis hæmorrhagica the process starts as serous imbibition of the dura mater, swelling of collagenous fibres, and proliferation of vascular adventitia with accumulation of pigmented histiocytes This is followed by larger intradural hæmorrhages which spread in the plane of the dura, and lead to the formation of neomembranes, finally a dural blood sac is formed There is little or no evidence of organisation The capillary proliferation in the areolar layer of dura mater with the formation of giant capillaries is conspicuous though not absolutely characteristic In addition to the vasoproliferative form of pachymeningitis hæmorrhagica—for which Aschoff's designation "pachymeningosis hæmorrhagica" is probably more appropriate—there are (as Jores and Laurent pointed out) cases with primarily fibrinous or fibrino hæmorrhagic exudation and much cellular infiltration In a few cases only it seems that a primary intradural hæmorrhage associated with a subdural hæmatoma *leads to a chronic pachymeningitis hæmorrhagica* In the clinical history of patients with pachymeningitis hæmorrhagica, trauma is absent or insignificant

At first sight it seems surprising that the dispute could go on for a hundred years, but most of the workers had only one type of material Moreover, the difficulty in the interpretation of histological findings in dural or subdural lesions can be well understood from the account by Russel and Cairns [26] of their investigation of 4 cases of metastatic neoplastic infiltration of the veins in the dense layer of dura mater *This obstruction resulted in engorgement* and rupture of the blood vessels in the inner layer and bleeding not only into the areolar tissue but also into the subdural space Thus a pathological process primarily located in the dura mater gave rise to a subdural hæmatoma As Hamperl [27] says, subdural hæmorrhage and chronic pachymeningitis may lead to almost indistinguishable end-results, but *it would be a mistake to* consider them as identical disorders from the beginning

FINDINGS IN INFANTS

Unfortunately all the cases of Link and Schleussing, and nearly all Gellerstedt's, were in adults In many regards findings in infants are illuminating Acute subdural hæmorrhage as the result of birth injury has been described [28 29] It is seen mainly in full-term and post mature infants, either in forceps delivery or with a disproportion between *the size of the head and that of the* birth canal It is due to bitemporal compression with elongation of the falx cerebri and pull on the tentorium At the same time the parietal squamæ overlap, one usually being shifted anteriorly over the other This results in kinking and often rupture of the pial veins as they pass from the arachnoid through the subdural space into the superior *longitudinal* sinus [30] Possibly in some cases the "bridging veins" (which cross the subdural space into the dura outside the sinuses in about a third of *the population*) are the source of hæmorrhage From this description it is understandable that the subdural hæmatoma of the newborn is almost always associated with tears in the upper layer of the tentorium (usually near *to the margins of the incisura tentorii*) and with a layer of blood on the upper tentorial surface Blood may or may not leak into the infratentorial space By gravity, the blood accumulates in the *posterior (temporo parieto-occipital)* regions At necropsy the subdural hæmatoma may either cover the whole vertex or be localised in the posterior regions If the hæmatoma is not immediately fatal, the common outcome is complete absorption leaving only rusty, reddish-brown spots on the inner aspect of the dura mater in the temporo-parieto-occipital regions, on the upper aspect of the tentorium and usually also in the middle cranial fossa Contrary to some opinions, absorption does take place from the subdural space, and there is a rich network of lymphatics in the outer subperiosteal layer of the dura mater [31 32] Usually the residua of neonatal subdural hæmatoma are incidental findings or the infants are admitted to hospital with feeding difficulties When infants with moderate subdural hæmatoma die in the neonatal period from other causes, a few reddish-brown, thin, neomembranes like spiders' webs may be found in the same place

Subdural hæmorrhagic effusions in premature newborn infants are different in nature They arise from rupture of the distended arachnoid, enormous amounts of thin hæmorrhagic fluid, which have accumulated in the subarachnoid space, pour into the subdural space If not fatal immediately, such hæmorrhagic effusions are absorbed without residua

Another form of subdural hæmorrhagic effusion of which the mechanism can be clearly understood is that associated with diffuse atrophy of the brain In children this is usually Tay Sachs idiocy [33] or Alpers's disease (progressive diffuse degeneration of cerebral grey matter) [34] If the infant survives for some time, neomembranes are seen on the inner aspect of the dura mater over the whole vertex, and there is a patchy thickening of dura mater which may involve the walls of the dural sinuses (mainly the superior longitudinal) leading to stenosis and eventually thrombosis *Here the obvious explanation is the pressure difference and effusion e vacuo*

Entirely different in clinical aspects and localisation, and often difficult to interpret in histological findings, is the pachymeningitis hæmorrhagica interna of infants [35–38] The disease is seen mainly between the fourth and eighth months of life The infants are usually underweight, sometimes suffering from diarrhœa and occasionally from scurvy or a hæmorrhagic nasal discharge The illness is usually chronic, starting with a slow enlargement of the head The enlargement is usually uniform and globoid, unlike that seen in internal hydrocephalus The fontanelle is bulging Vomiting, crying, and somnolence are common The infants may develop a hydrocephalic facies with the eyes directed downwards Retinal hæmorrhages are the rule in these children, though rare in the pachymeningitis of adults Occasionally the onset is acute, or even fulminating with symptoms like those of acute purulent meningitis, in some of these cases the acute symptoms subside, and the illness takes the chronic form At necropsy the lesions are typically fronto parietal and almost always bilateral A subdural tap in the lateral angle of the fontanelle is therefore almost always successful, though it is not in the subdural hæmatoma of the newborn. Cysts are found with one or many locules filled with a hæmorrhagic and xanthochromic fluid, and thin reddish-brown membranes on either aspect of the sac. The dura is seen to be altered on histological examination. There are wide capillaries in the areolar layer, though "giant capillaries" are not as conspicuous as in pachymeningitis of the adult. Occasionally the condition is associated with internal hydrocephalus. Pigmentation of the dura in the temporo-occipital regions and on the upper aspect of the tentorium is rare, and pachymeningitic cysts are not seen on the upper lamina of the tentorium, where in birth injury tears are common. These findings, together with the clinical course and symptoms, exclude birth injury with subdural hæmatoma as the origin of this disease. It is very unlikely that it is caused by traumatic intradural hæmorrhage. Such hæmatomas are extremely common between the two dural layers of the tentorium, they are harmless and resorbed without any residual changes, but in sites where hæmorrhagic pachymeningitis is common they are practically never seen in infants dying from birth injury in the first few days of life. It is noteworthy that scurvy (in which an alteration of the ground substances of connective tissue is well known) is fairly commonly associated with pachymeningitis, but no association with hæmorrhagic disorders has been found. Walthard[39] has reported a capillary proliferation close to the inner aspect of the dura, similar to that seen in pachymeningitis hæmorrhagica, in laboratory animals on diets deficient in vitamin B_1. The high incidence of alcoholism in pachymeningitis hæmorrhagica of adults may be related to this. Various causes may lead to degenerative, vasoproliferative, and inflammatory changes in the areolar layer of the dura mater and thus to pachymeningitis hæmorrhagica interna.

TREATMENT

In treatment, the surgical approach described by Ingraham and Matson[21, 22] seems to be the method of choice when there are appreciable amounts of clotted blood in the subdural space. For pachymeningitis hæmorrhagica interna with cysts which grow slowly in size, conservative treatment will be preferred by most pædiatricians. Beneficial results, with absorption of fluid, were reported[40–42] after aspirations of subdural fluid in addition to administration of antibiotics or vitamins, or both. Freislederer and Schweier[43] have now reported encouraging results using hyaluronidase in infants with verified pachymeningitis hæmorrhagica. This enzyme, one of the spreading factors, is known to catalyse the depolymerisation of mucopolysaccharides of ground substances, to increase the permeability of capillaries[44] and fascial membranes,[45] and to facilitate the absorption of subcutaneous fluid.[46, 47] Accepting the theory of Gardner[17] and others, Freislederer and Schweier injected hyaluronidase into the dural sacs expecting to alter the physico-chemical properties of the semipermeable membranes and promote a rapid absorption of the encysted fluid. They treated in this way 9 infants aged $3^1/_2$–12 months. In all of them the pachymeningitic cysts disappeared, and all gained in weight.

In England Now

A Running Commentary by Peripatetic Correspondents

NOT for me sightseeing in Europe, cruising in cargo boats, or even sampling Spanish food. For 14 carefree, phoneless days I forgot I was a G.P. and along with a dozen others became a budding artist. We assembled at Rock on the North Cornish coast and, from a comfortable hotel, sallied forth daily, our Irish tutor in tow, to paint the coast-line if not exactly red most other colours. Budding artists are a mixed bunch and we ranged in age from Arthur, aged 74, who painted exquisite water-colours during the day, at night regaling us with cups of tea, and Betsy, just starting in oils and the proud possessor of four grandchildren and a bubble-car, to George, Ruth, and Mary in their early 20s who came because they loved a painting holiday. We took our work seriously and our day began about 9.20 when the elder members of the party did their daily dozen by sprinting for the bus whose time of departure was as variable as an English summer. We painted till lunch with Paddy, our tutor, who swore he could teach anyone to paint, instructing, extolling, and encouraging all in turn. We painted till tea and if we wished we painted till dinner and the sun still shone. Almost before we knew we had started the holiday was over. Between us we had produced getting on for 150 pictures. We may not all reach exhibition standard, but by the end of that fortnight we discovered a new way of expressing ourselves which though by no means perfect gave infinite pleasure to the doer. And miraculously Paddy was right: WE COULD PAINT.

* * *

Hallo, Sarah. Take a seat. How can I help you?

Aren't you busy, doctor! I've been waitin' for an hour and your room is still full . . . but I won't keep you long, I said to Nelly "'e's got enough to do." But she said 'Get yourself along or I'll call 'im round.' So I come right over from work . . . you'll excuse my workin' clothes. Well it's this 'ere. For a long time when I've been walkin' I get a little . . .

A little mazy?

No. I wouldn't say mazy. It's all down this side, an' I get a . . .

A pain?

No, it's not a pain.

More of an ache?

You wouldn't rightly call it an ache. It strikes 'ere then it travels 'ere an' strikes through to the back an' up my neck an' leaves me feelin' cold an' 'ot.

Cold or hot?

Cold an' 'ot . . . if you know what I mean, an' then of course my bowels don't improve.

Still stubborn?

Just the other way!

Oh. Well I can give you something for that.

Are you writin' somethin' out for diarrhœa?

Well . . . yes.

But it's not the diarrhœa I've got . . . not really. I can be that way one day an' just the other the next. That's what I was tellin' our Nelly. I said 'It's not natural. There's somethin' sadly wrong." I said. So I come right over. Do you remember them pills you gave me?

Er . . . the white ones?

No, the red.

I don't seem to have written them down. When did I prescribe them?

I met you in the market one day an' you 'ad your scripts with you an' you wrote me down for a course of 'em an' said they was just what I needed.

Of course. Of course. You were run down.

That's it.

A bit anæmic . . . and a bit chesty?

Yes I was.

And your stomach was off?

That's right. I was tellin' Mr Hudson the butcher about my wind just before you came along.

Yes I remember, Sarah. And you were hot and cold and faint and sick. You can have some more with pleasure.

I was just goin' to say, doctor.

How many do you want, Sarah? 50? 100?

I was just goin' to say, doctor . . .

I'll give you 100, it will keep you well stocked. No use making extra journeys to the surgery. You are busy enough I am sure.

I was just goin' to say, doctor

Yes, Sarah?

Are you givin' me a recipe for them tablets ... the same ones?

I am indeed ... exactly the same ... er ... that's what you want isn't it?

No please, doctor. They were very good but they made me sick an' they didn't really relieve the

The pain?

Well you wouldn't call it a pain

* * *

My friend has an inbred politeness which makes him unable to assert himself in small matters. His wife and he were at a London theatre and, just before the play started, his nose began to bleed. His technique, developed over the years, is not to fuss but hold his head over a basin and soon the bleeding stops. When he felt it coming on he accordingly left his seat and proceeded to a wash-basin. There the dripping went on as usual and was beginning to get less when a voice behind him said "Ah! a nose-bleed. I'm a doctor. I'll stop that for you." My friend protested, probably a little at a disadvantage with head forward and having to be careful where he aimed the blood, that he was quite all right, was used to it, and that it would soon stop. The energetic doctor quickly returned with cotton-wool and despite spluttering protests proceeded to pack each nostril with what could have been an excess of therapeutic zeal, for when he had finished the patient said, in retrospect, he felt that his head was full of cotton-wool, and he felt faint. He asked if he could have a glass of brandy, a traditional syncopal remedy in which he had much faith, but the doctor said certainly not and that orange juice was the thing for him. Orange juice is anathema to this particular epistaxian, but having been shaken and probably speaking even more indistinctly he was unable to make this plain and at the point of the stethoscope he ingested a large glass of orange juice. The doctor disappeared.

My friend saw the play without pleasure, being more concerned, he says, with his endogenous throbbings in the head than the emotional ones on the stage. When he returned home that night he couldn't remove the cotton-wool which had been well and truly packed and being a considerate person sat with his head in his hands all night because of his discomfort before calling his own doctor in the morning.

* * *

In the routine history I asked: "Do you ever get short of breath?"

"Only since I've been doing my present job."

"And what is that?"

"Carrying gas cookers."

"Oh. Well, how many stairs can you climb before you get breathless?"

"Oo, carrying a gas cooker, only about three flights."

* * *

My patient, an elderly lady with a broken hip, shares a room in hospital with a younger lady who has recently undergone pelvic surgery. Weaning the latter from her catheter has been difficult and two days ago her doctor tried hypnotic suggestion. She still has her catheter. But *my* patient complains that she should have been given ear-plugs—she has had frequency ever since.

* * *

I had some difficulty in making my American friend understand how to get to his destination.

"You take the left fork at the doss house," I explained.

"What is a doss house?"

"A doss house is a place where tramps put up for a night."

"What is a tramp?"

"A vagrant, a vagabond, wayfarer, loafer ..."

He looked at me blankly.

"A hoofer, a hobo, someone dressed in old clothes with a straggly beard who lives on the road," I continued desperately.

"Now I get you," he exclaimed at last. "You mean a bum."

Science Fiction Footnote.—He chemotaxied towards her and took her in his arms.

Letters to the Editor

CONSULTANT AND SPECIALIST

SIR,—Your article and leader of June 1 are well timed and should instil a sense of urgency into those responsible for our hospital services.

Stated simply, the problem is that our present hospital provision does not meet the needs of outpatient consultation and investigation or inpatient treatment. There are nearly 500,000 people on our waiting-lists, patients and practitioners weary of waiting for outpatient consultations, and senior registrars, trained to deal with this situation, are unable to find a satisfying outlet.

There is a great disparity of consultant distribution throughout the country—the facts are known, but not published. You, Sir, must have obtained some insight into these in your recent partial survey. The Ministry will not reveal the recommendations made by working parties of senior consultants in each region some five years ago and the Consultants and Specialists Committee does not appear to have been very insistent in demanding this information. In many areas there is known to be resistance by the profession to the appointment of more consultants. Our traumatic service cannot deal adequately with a rising accident-rate, but the resistance to proposals for remedying this is mainly medical.

The situation is urgent. Many in the profession feel unable to voice their opinions openly. Consultants, in part, because the system by which merit awards are made discourages outspokenness, while senior registrars and their juniors obviously cannot put themselves in a position which diminishes still further their meagre chance of promotion.

There is need for change and this can only come from outside the present administration. General-practitioner distribution is being ensured by statutory means. It is essential for Parliament to set up a committee forthwith to obtain the facts, so carefully guarded, and to make recommendations for immediate implementation.

This would ensure that "waiting" is not regarded as normal for our hospital population and that senior registrars get the consultant appointments for which they have been trained.

Central Middlesex Hospital,
London, N.W.10.

HORACE JOULES.

SIR,—Your leader (June 1) and the correspondence arising from it have been headed Consultant and Specialist. It may be that at least some of our present discontents are linked with the circumstances which have caused this distinction to be created.

In the days before the National Health Service, a patient looked in the first place, for medical advice and help, to his personal or family doctor, who gradually, as a consequence of the rise of specialism, came to be known as a general practitioner. When this personal medical attendant felt that he needed a second opinion, he called in a specialist of his choice, with whom he went into consultation. This was a conference between practitioners who were regarded as collaborators, and it was the personal attendant, and not the second opinion, who took the responsibility for the action which ensued from the meeting. If the patient could afford to pay for the specialist's opinion, he was expected to do so, but if he could not, it was usual for him to go to a hospital or clinic at which the specialist gave his services freely, and as a consequence became known as an honorary surgeon or physician as the case might be. In some hospitals, each specialty might have more than one honorary accredited to it, and in such cases the senior honorary was designated accordingly. His juniors were specialists as he was, and in due time would probably step into his position. In the meantime, private consulting practice was open to the junior

The point is that in that period a practitioner was called a specialist because he practised a specialty, and when the word consultant was applied to him, it carried no implication that other specialists were of lower rank or had need of his supervision, although it was open to them to consult with him in a particular case if they so wished.

With the advent of the health service, the word "honorary" was no longer appropriate, and since the specialists concerned saw only patients referred to them by general practitioners, they were given the title "consultant." At the same time it was realised that some hospitals, mostly of the long-stay type, were giving treatment which was appropriate to the needs of the patients but could not be considered the practice of a specialty, and in others the assistant medical officers were working under the immediate supervision of a medical superintendent; and as a purely temporary expedient the title "senior hospital medical officer" was coined for such officers. At that time the criterion was the nature of the work carried out by the holder of the post, not his personal qualities or academic attainments; in short, "the rate for the job," and it would be difficult to quarrel with this principle.

At that time the consultant appeared to be in line of succession to the pre-1948 honorary, and the S.H.M.O. was the successor of the hospital medical officer in the employ of local authorities and similar bodies, who provided treatment for patients who were in hospital for such long periods that they could no longer be regarded as being under the care of their own private or panel doctors.

In the Terms and Conditions of Service of Hospital Medical and Dental Staff, published on June 7, 1949, S.H.M.O.s were defined as "senior officers performing clinical duties who are not of consultant status but not registrars." At this point it became clear that the criterion which defined the S.H.M.O. was not the nature of the work but the assessment of the holder of the post. On Oct. 5, 1950, circular R.H.B. (50) 96 appeared, and it became clear that the S.H.M.O. was now to be regarded, not as a senior practitioner who worked in hospital, but as a grade of specialist beneath the rank of consultant and therefore suitable to be an assistant grade which would have the function of extending specialist treatment to fields which the existing consultants were not sufficiently numerous to cover, but which could be said to have consultant cover by reason of the supervision which the consultant was presumed to exercise over the S.H.M.O. At this point it became clear that the original understanding—that the S.H.M.O. grade was a temporary one which would tend to die out as the National Health Service developed—had been dropped.

There is a widespread impression that it is proposed to perpetuate a species of subconsultant specialists in grade III of the Strachan proposals, at a rate in which the maximum would be comparable with the starting remuneration of the most junior consultant. It is difficult to imagine that any practitioner would accept this subordinate role as the summit of his ambitions. At present S.H.M.O.s constitute more than a third of the total specialist body, and if the impression is well founded they might approach parity in numbers. The last paragraph of your editorial asserts that it is baseless to harbour a fear that the Ministry might ruthlessly seek to swell the ranks of specialists with the aim of securing cut-price consultants. Whether this is the Ministry's aim is irrelevant. It would be the logical outcome if this impression proves to be well founded.

Cambridge C. B. V. WALKER

SIR,—I should like to support Dr. Herford's views (June 15) which in many ways go to the rock bottom of our principal troubles in the National Health Service as it exists today.

If general practitioners had the time and the inclination to do for their patients *themselves* all the work for which they were trained—to accept continuous care for them under all circumstances and all conditions, whether of body or mind, from the time they come on their lists till they depart or die, if or when that becomes so, then *out*patient departments could become mere shadows of what they once were. Consultants and specialists could at long last have ample time to devote to those patients who were really in need of the services of a man of consultant rank, with consequent enormous saving in the administration.

With all due respect, Sir, I must entirely disagree with you when you suggest the appointment of assistant physicians and surgeons.

Having made a special study of the working of the National Health Service since its inception, I am convinced that you may have the finest hospital and specialist staff in the world; but if you have not got a first-class general-practitioner service as well you can no more wage a successful campaign against disease than can the general commanding an army in battle, who has been given a first-class team of experts to help him, but whose fighting troops are of poor quality.

Worthing HAROLD LEESON

SEX DIFFERENCE IN GENETIC RISKS OF RADIATION

SIR,—Many authorities on radiogenetics, among whom Muller is one of the most prominent,[1–5] believe that increased radioactivity of the external medium, as a result of nuclear tests and of the peaceful utilisation of "heavy" nuclear energy, will prove detrimental to the future of the human race by unbalancing the ratio between the rate of mutations and the rate of eliminations.

It is highly regrettable that humanity should waste enormous amounts of technical skill, money, and fissile material in merely destructive fields. Let us hope that in not too remote a day, common agreement of the great nuclear powers will stop this nonsensical bomb race.

Nevertheless, the industrial use of atomic power faces humanity with serious problems, among which radioprotection is not the least important. I think that the present maximum permissible dose of ionising radiation (0·3r per week, which amounts to about 300–350r for the entire reproductive period of the human individual) is too high and needs urgent revision.

But the possible genetic damage from irradiation may not be equal in both sexes. From a close scrutiny of the biology of reproductive cells of both sexes, it seems probable that male gametes are not so liable as the ova to transmit acquired radio-induced mutation.

If we accept that the spontaneous mutation-rate found in mice is applicable to man, then one gene mutation per 40,000 gametes is likely to have little effect on the descendants,[6] since millions of spermatozoa are produced, and only one (and we may suppose it the best qualified one) is accepted by the ovum. A monogenic mutation is likely to be transmitted only if the vast majority of male gametes bear it. Rare monogenic or oligogenic mutations of the kind produced by ionising radiations, are likely to affect the biology of the bearer in such a way as not to permit it to compete with its brother gametes.

On the other hand, the maturation-rate of spermatogonia and spermatocytes is so high that the accumulation of irradiation seems less perilous than for the female sex-cells. The production and elimination of the ova is a slow process, during which radiations have time to act. Only one ovum takes part in the act of reproduction.

---

1. Muller, H. J. *Acta radiol., Stockh.* 1954, 41, 5.
2. Muller, H. J. *Science*, 1955, 121, 837.
3. Muller, H. J. *J. Hered.* 1955, 46, 199.
4. Muller, H. J. *Bull. atom. Sci.* 1955, 11, 329.
5. Muller, H. J. *Sci. Amer.* 1955, 193, 58.
6. Sturtevant, A. H. *Engng Sci.* 1955, 18, 9.

The rate of maturation is slow, therefore the damage due to accumulation could be greater, and the dimensions of the cell make it a bigger target for ionising particles

On the other hand, there is a well-known direct relationship between radiosensitivity and the metabolic state of the cell, and ovogenesis is a much slower process than spermogenesis, but the ages of the cells are equal, *and in the premeiotic stages their nuclei play similar* rôles

I think that women are more exposed to the genetic hazards of the increasing radioactivity of their surroundings and that there should be different standards for the maximum permissible dose of irradiation for each sex

Sanitarium Craiova, Rumania

EUGEN J ALTESCU

RADIATION AND INFLUENZA MUTATION

SIR,—Mr Pirie's suggestion (June 15) that the mutant strain of the influenza virus which is causing the present epidemic in the Far East may be the result of the nuclear-weapon tests in the Pacific is difficult to refute, if only because of the logical impossibility of proving a negative It would be equally difficult for him to disprove that the mutation is not the consequence of any other cosmic event—e g, the arrival of a particle of extremely high energy from outer space, such as has been recently reported from the Massachusetts Institute of Technology We are therefore left with probabilities, and as it is notorious that the influenza virus is more liable to spontaneous mutation than almost any other virus, it would seem unnecessary to invoke any special circumstance to account for the appearance of this particular mutant strain

The Eastern origin of the epidemic is by no means unique and cannot be attributed to any sinister effects of the weapon tests Every schoolboy must know that the Black Death came from the East, and most practitioners are aware that the majority of the pestilences which have ravaged Europe in the past have originated in the East There is much evidence which points to the East as the home of nearly all the infectious diseases which have afflicted and still afflict us

London, W 1

E J MOYNAHAN

THE CHILD'S RIGHT TO ADOPTION

SIR,—Miss Hunter's letter of June 15 raises some interesting points

I would agree with her that there are a large number of unwanted legitimate children, but wonder very much why she thinks that to have these children adopted would solve the situation

Psychologically the evidence would certainly not seem to support such a hypothesis The crux of the children's emotional disturbance as evidenced by their behaviour disorders or neurotic or psychosomatic symptoms lies in the fact that they are not wanted by the parents who have them and one repeatedly finds that adopted children vent the insecurity which is the result of this situation on the adoptive parents and become their problem This was clearly expressed by one such child who said "The fact they loved me made me feel worse—why was I not loved by my own mother and father?" It is often also true that the children vent the hate and aggression that really belongs to the rejecting natural parents against the adoptive ones, and try to force them to repeat the original situation

In thinking of this problem, I would like to comment on another point It seems to be assumed that all persons wanting to adopt children have "good" reasons for doing so and will make "good parents" Many of them, I would feel, in fact want them to appease their own sense of failure, and at once reject the child who does not fulfil their sometimes irrational demands for intellectual and social qualities that do them credit Such people make bad parents, but although great care is taken that adoptive parents shall be given "satisfactory children," less is taken that the children shall be given "satisfactory parents"

Department of Psychiatry,
University of Leeds

W MARY BURBURY

CARDIAC ARREST WITH FLUOTHANE

SIR,—Since I have in preparation a report of 25 selected cases of cardiopulmonary disease, which include conditions such as congestive heart failure and fulminating *thyrotoxicosis*, successfully anæsthetised with 'Fluothane' (halothane), I would like to comment on Dr Foster's letter of June 1

In my experience fluothane has proved entirely safe when used in concentrations of under 2% Safety is increased by the use of an inhaler giving precise vapour percentages The 'Fluotec' (Cyprane Ltd), a temperature-regulated inhaler, delivers a vapour of from 0 5 to 3% at gas flows of 4 to 10 litres a minute Concentrations of 0 5 to 0 8%, which do not materially affect blood pressure or pulse rate, are sufficient for all operations where muscular relaxation is not required, provided it is not intended deliberately to lower the blood-pressure For operations in the pelvis or lower abdomen 1 2 to 1 5% produces sufficient muscular relaxation This strength has not normally affected blood-pressure or pulse-rate to an extent necessitating intravenous atropine for bradycardia or methoxamine for hypotension, when hyperduric atropine has been used in premedication

The safety factor has been carefully studied by Raventos in animal experiments[1]

> *In dogs a vapour strength of 3 6% produced respiratory* arrest in 60 min, but cardiac arrest did not occur for a further 9–10 min In another experiment 4% vapour produced respiratory arrest in 9 min Artificial respiration was continued for a further 90 min at this concentration This produced a decrease in voltage of QRST complex, but the heart continued to beat regularly

Very precise control of vapour strength is essential in the use of fluothane I think that Dr Foster has probably been instrumental in preventing accidents with this drug and I should like to congratulate him on his frankness in reporting this case

Crewe and District Memorial Hospital
Crewe

E S POPE

SIR,—'Fluothane' (halothane) is a potent anæsthetic agent and in my opinion a valuable addition to our armamentarium Because it is so potent—2% or less of fluothane vapour sufficing for anæsthesia in the great majority of subjects, while 3% should not be exceeded —it is essential *that it should be administered* via an apparatus which enables one to control the strength of the mixture delicately and accurately There is at least one inhaler on the market which does this the ether bottle of the Boyle mark 2 circle absorber, which was designed to provide high concentrations *of ether* vapour, certainly does not

In an attempt to reproduce in the laboratory a mixture similar to that used by Dr Foster (June 1), I connected a sine curve respiratory pump to a Boyle mark-2 circle absorber and adjusted it to give a stroke of 500 ml sixteen times a minute Just under 2 oz of fluothane were placed *in the* ether bottle and the control turned to the sixth notch Samples were drawn by suction from the facepiece end of a corrugated tube through a Rayleigh gas interference refractometer In 60 sec the concentration of fluothane rose to 11%, in 90 sec to 13%, and in 2 min *to 15%*

When the experiment was repeated with 4 oz of fluothane in the bottle the concentration rose to 12 8% after 60 sec and to 15% after 90 sec In clinical use the warm expired gases would presumably result in even higher figures These figures are some four to five times the maximum permissible clinical strength of 3%

H J **BRENNAN**

ORGANIC DISEASE AND SUICIDE

SIR,—To the layman, and to many doctors, suicide is a matter of mental rather than physical disturbance The customary verdict of the coroner's court is that the event took place "while the balance of the mind was disturbed," and this contributes to the exclusion of organic disease as a contributory factor

As the coroner is concerned only with the mode of death and with the state of mind of the deceased no report of organic disease present is made to the Registrar-General Consequently, the only source of information about them is the file of the individual pathologist My records over the past five years show 65 cases—a number which cannot be expected to provide accurate statistics, but will, perhaps, show that physical disease is important enough to warrant its inclusion in the coroner's certificate in many of the cases

In the series there are three groups

Group 1—No organic disease (21 cases) (32%)

Group 2—Organic disease which might initiate or enhance depression (19 cases) (29%)

(*a*) Arterial hypertension (12) In all there was massive hypertrophy of the left ventricle the heart weights ranging from 16 to 31 oz No valve defect was found In 1 case there was an adrenal cortical adenoma 5 cm in diameter

(*b*) Active peptic ulcer (4) The presence of such lesions in persons who have not sought medical advice may, apart from the stress induced by pain, foster the belief that there is a cancer

(*c*) Kümmell's disease (1) This man had had a severe crush fracture of the lower dorsal spine some years previously and progressive collapse of the vertebræ led to his being bedridden and in constant severe pain for many months

(*d*) Recurrence of uterine prolapse (1) This patient although in considerable discomfort, had declined to consider a further operation

(*e*) Cerebral thrombosis with hemiplegia, immediately following an abdominal operation (1)

Group 3—Organic disease possibly associated with depression (25 cases) (39%)

(*a*) Cholelithiasis (7) Of these 5 had large gall stones at necropsy, and 2 had recently had the gall bladder excised for stone

(*b*) Fatty infiltration of the heart (7) These showed a great excess of epicardial fat with penetration of the muscle of the right heart Only 1 was grossly obese and in the other 6 the condition appeared to be due to chronic bronchitis and emphysema In all there was certainly a severe restriction of physical activity

(*c*) Gross obesity (5) Advanced fatty degeneration of the liver was present in 1 case Here again there was a severe restriction of physical activity None of them could have walked upstairs without dyspnœa (In all, in the whole series, there were 11 examples of gross obesity)

(*d*) Thyroid disorders (nodular goitre 1, large adenomas 2) Apart from their toxic effects these may have been interpreted as cancers

(*e*) Enlarged prostate with hypertrophied bladder (1)

(*f*) Bilateral adrenal hypertrophy (1) The glands were about 3 times normal size

(*g*) Chronic hypertrophic gastritis (1) This may of course have been due to the misuse of alcohol

It may well be argued that there are large numbers of contented people with high blood-pressure that fat and jolly men can be found everywhere, and that a considerable proportion of the population goes to the grave with gall stones of which it has never been aware But the parade of pathology in these 65 persons indicates that organic disease in suicide is a matter of some importance, and deserving of further consideration

RELATIVES IN HOSPITAL

SIR —In your leading article of May 11 you referred to the necessity of providing for visitors Through the good offices of the former contributory scheme, it has been possible to provide, at this hospital, a hostel for patients relatives It is a modern bungalow and includes a double room two single rooms kitchenette, lounge, bathroom and two toilets Four people can stay overnight, and a larger number during the day in the spacious lounge No meals are provided in the hostel The relatives can obtain them either in the dining-rooms or in the staff canteen where they pay the normal charges

Occupants of the hostel are expected to look after their rooms, to make their own beds and generally to care for the place though the cleaning services are provided by the hospital Care is taken to ensure that the privileges are not abused, and when a ward sister is aware of a relative who genuinely needs accommodation the hostel is used It is not intended to provide lodging free of charge where people are able to pay hotel charges but in all deserving cases the services of the hostel are free

A second use to which the building is put is to accommodate nursing mothers whose infants are patients of the hospital Accommodation of these mothers has often in the past presented difficulty, even where, by arrangement, billets were available in the town Through the use of the hostel these difficulties no longer exist

Before the construction of the hostel records showed the potential demand for such accommodation, and the forecast has been entirely justified by the experience gained since it was opened It has been occupied constantly and within six weeks was in full occupation, though of course this will not be continuous

Lack of capital funds prohibit such provision from normal resources but a scheme like this should be well within the target of most Leagues of Friends

AN "OUTBREAK" OF CORONARY-ARTERY DISEASE

SIR,—Since the beginning of the year we, in the course of our work as general practitioners seem to have struck a very peculiar "epidemic" and we should be interested to learn whether any other doctor has had a similar experience

About the middle of March it occurred to us that we were seeing an unprecedented number of cases of angina and coronary occlusion The patients many of whom up to then had rarely complained of any serious illness had at some time in January suffered from an illness which we had labelled "influenza" They had complained of severe malaise ("feeling awful"), unusual tiredness, and occasionally sharp supra orbital pain They looked very ill but had none of the aches and pains of true influenza They had a brown furred tongue, a variable temperature and a basal bronchiolitis but nothing else Seven to ten days later the picture changed to that of a very resistant bronchitis and sometimes to a severe broncho pneumonia

When they appeared to be recuperating and even after apparent recovery, they began to complain either of retrosternal pain radiating to the throat or precordial pain, or pins and needles radiating to the left shoulder and to the little finger, relieved by rest, and associated with temporary but striking fall in blood-pressure In a few, a full coronary thrombosis developed At this stage through the kindness of the casualty officers of St Bartholomew's Hospital some electrocardiograms were done and the reports often read "The tracing is an unusual one of the S1, S2 S3 type" In some cases there was slight depression of the S T segments in leads 2 and V6 Six had definite evidence of small cardiac infarcts Three others died of coronary thrombosis

In all cases whether the patient developed cardiac symptoms or not he sooner or later had signs or symptoms which we attributed to liver insufficiency—muddy complexion, flatulence abdominal discomfort and much hepatic tenderness but no obvious jaundice, though the urine with colour varying from orange to dark brown gave positive froth and sulphur tests and the stools were often pale , but both changes were transitory

Still under the illusion that this was some obscure form of virus A influenza, we approached the director of the Central Public Health Laboratory, Colindale, who very kindly investigated the bloods of about a dozen of these patients for a virus infection, but was unable to arrive at any definite conclusion

Men and women were equally affected, sometimes more than one in a family Most were over the age of 40 Those with a tendency to cardiovascular disorders seemed to be more readily affected and were often left with a varying degree of permanent damage We have traced a few children whose bouts of peculiar malaise and unexplained pyrexia seem to us in retrospect to fit in with the same sequence of events

Treatment consisted of salicylates and antibiotics in the acute stages, with symptomatic treatment later on

In view of the seriousness of the sequelæ, we should like to know whether any other doctor has had a like experience, and whether anyone can offer an explanation of this "epidemic" of coronary-artery disease ?

We should like to point out that in this district coronary and general arterial disorders are very common, and that one of us (J Z) has, in fact, been following up a series of cases of cardiovascular and hypertensive disease for the past eight years, hence the sudden appearance of an unusual number of acute cardiac cases was all the more striking

CIRCUMCISION WITH BONE-CUTTERS

SIR,—I think it would be unfortunate if the advocacy by Mr Skegg (June 8) and Mr Crossling (June 22) of the bone forceps technique for circumcision was allowed to pass without reference to a serious objection to the method—namely, the removal of an inadequate amount of the lining mucous membrane of the prepuce The fusion of the residual mucous membrane, which is still able to cover the greater part of the glans penis, to the preputial skin is liable to be followed by a severe degree of postoperative phimosis and a revision of the circumcision may become necessary The fear of this unfortunate and avoidable complication no doubt accounts for much of the unpopularity of the method in this country

Leamington Spa,
Warwickshire

C R SAVAGE

TREATMENT OF MIGRAINE

SIR,—Without any desire to discuss the theories current about the cause of migraine, or indeed sufficient knowledge to enable me to do so, I nevertheless am led, after investigation of a sufferer in whom I take a deep interest, to mention one point for the benefit of those who, like most of us, have to treat patients in a symptomatic way—a point which does not seem to be sufficiently remembered

In this patient, at the beginning of an attack, the pylorus shuts completely, so making the swallowing of drugs entirely useless, since they simply stay in the stomach until the attack is over I should imagine that this condition is fairly common, judging from statements from other patients If this is so, drugs taken by mouth might as well be thrown at once into whatever receptacle the patient seizes when vomiting starts, as it usually does

For this patient nothing has been of any use in stopping an attack until he tried hypodermic injection of ergotamine tartrate or some of the barbiturates, which are useful sometimes as a change Recently, however, a chlorophenothiazinyl propyl - methyl - piperazine derivative ('Stemetil') has been advocated for the control of migraine My patient finds it of no use when taken alone, but it does control vomiting, apparently by keeping the pylorus open, and he finds that four 5 mg tablets with a 2-mg tablet of ergotamine tartrate, if taken as soon as the premonitory feeling comes on, will stop an attack If the attack has been allowed to develop further, as may sometimes happen when it starts during sleep, a second or third dose of both may be taken

I intend to try the effect of following the stemetil by some of the more ordinary sedatives, but meanwhile I hope that this letter may help to relieve those who have frequent attacks of migraine

I am very grateful to Dr C W Walker, of Hereford for bringing this drug to my notice

Hereford

D S SPENCE

CHRONIC LYMPHATIC LEUKÆMIA AND THE NEPHROTIC SYNDROME

SIR,—Dr Bodley Scott (June 8) reported for the first time the association of the nephrotic syndrome in two patients suffering from chronic lymphatic leukæmia Amyloidosis involving the kidneys was responsible for the syndrome in one of these patients He recalls that amyloidosis is seen occasionally with myelomatosis and suggests that this forms another link between myelomatosis and chronic lymphatic leukæmia

In the past twelve months I have seen two examples of the nephrotic syndrome due to amyloidosis—one occurring in association with chronic lymphatic leukæmia and the other with Hodgkin's disease

CASE 1 —Six months before his death, a man of 47 was found to have an early form of chronic lymphatic leukæmia Blood examination Hb 13 1 g per 100 ml , red cells 4,400,000 per c mm , white cells 23,100 per c mm (polymorphs 47 5%, lymphocytes 46 5%, monocytes 5 5%, eosinophils 0 [illegible]), platelets 271,000 per c mm The marrow showed a moderate increase in small mature lymphocytes Serum protein total 4 5, albumin 2 4, globulin 2 1 g per 100 ml Electrophoretic pattern of the proteins showed no characteristic abnormality No treatment was given for the leukæmia A few weeks before death considerable œdema of the extremities and gross proteinuria developed

Necropsy —Considerable amyloidosis of liver (2450 g) and spleen (510 g), and smaller amounts in marrow, lymph nodes, and suprarenals Congenital absence of right kidney Cystic disease and considerable amyloidosis of left kidney Moderate leukæmic infiltration of liver, spleen, marrow, and lymph nodes

CASE 2 —Two years before death, a man of 29 complained of night sweats, anorexia, and loss of weight There were no significant abnormal signs, and investigations failed to find a cause for the pyrexia Eighteen months later he complained of low abdominal pain and a pelvic mass was palpable Laparotomy revealed a mass of firm lymph nodes encircling the left common iliac vessels Histological examination of one of these nodes showed Hodgkin's disease The blood and marrow pictures were normal Serum protein total 8 9 albumin 3 9, globulin 5 0 g per 100 ml Electrophoresis showed no demonstrable abnormality of the globulin fraction

A total of 30 mg of nitrogen mustard ('Trillekamin') was given intravenously, in five divided doses Four months later severe anæmia, diarrhœa, and anorexia developed and there was further loss in weight Peripheral œdema was extensive and there was a heavy proteinuria (Esbach, 20 g per day) Serum protein total 3 3, albumin 1 0, globulin 2 3 g per 100 ml

Necropsy —Considerable amyloidosis of liver (3450 g), spleen (280 g), kidneys (340 g each), and suprarenals Hodgkin's disease of lymph nodes and spleen

Teilum [1] recorded the induction or enhancement of amyloidosis by nitrogen mustards, cortisone, and corticotrophin in mice treated with subcutaneous injections of sodium caseinate Teilum believes that a suppression of mesenchymal cells which are in a state of active proliferation is involved in the basic mechanism of the formation of amyloid This theory is further supported by reports of Hodgkin's disease in man treated by nitrogen mustard in which amyloidosis rapidly developed [1 2]

In case 2, nitrogen mustards were given for the Hodgkin's disease and this was followed by amyloidosis

Purists may like to note that *homotope* would be more exact, Soddy, however, gratefully adopted the suggestion of isotope, and its use in its now accepted sense was first published by him in 1913

To commemorate the coming of the radiochemical word, the Glasgow and West of Scotland section of the Royal Institute of Chemistry is making arrangements to affix a plain lettered plaque bearing the names of Soddy and Dr Todd to the house concerned This house is now the property of the University of Glasgow, and the arrangements are being made with the consent and support of the University authorities No public appeal for funds is being made

Influenza

INFLUENZA-A virus, provisionally identified as the Far Eastern type, has been isolated from several Pakistani seamen lately arrived in this country The seamen fell ill after they had been flown to this country to man a ship in London The virus has apparently established itself in North America The disease has appeared among men of the United States Atlantic destroyer force at Newport, Rhode Island, and it is reported [1] that none of the crews affected had been in contact with persons from the Far East The infection may have spread indirectly via Europe At Newport about 550 sailors aboard eight ships were said on June 21 to have been infected The disease lasted three or four days and the main features were severe headache, fever up to 104°F, and aching muscles Military transports docking at Californian ports have had influenza aboard

Speaking at a press conference in *London* [2] *on June 18*, Sir Macfarlane Burnet referred to the changes in the quality of the virus that took place every five to ten years The last sharp change had been in 1946–47 The new type of virus might also continue for five to ten years, but after the first wave it would settle down to become " just ordinary influenza " Sir Macfarlane added that Australian laboratories would be ready to begin commercial production of a vaccine last week Laboratories in other countries would also be preparing a similar vaccine (the Wright-Fleming Institute of Microbiology is doing so in London), but in Australia it had been an urgent matter because of the onset of winter Nothing more extensive was contemplated than the vaccination of hospital nursing staffs and those in regular contact with travellers Unless a country was prepared to take extreme measures, Sir Macfarlane said, it would not be possible to keep the infection completely at bay because of the new virus type

A report from Holland [3] suggests that the new virus *may be related to the one* which caused the pandemic of 1889, since antibodies against it have been found only in people over 70 years of age

Poliomyelitis

Uncorrected notifications of poliomyelitis in the week ended June 15 (24th week of the year) were as follows (previous week in parentheses) paralytic 41 (48), non-paralytic 12 (26), total 83 (74) The following figures compare this year's notifications with those in the preceding nine years

Year	*Total cases up to and including 24th week*	*Cases in 24th week*
1948	612	15
1949	421	38
1950	933	93
1951	641	50
1952	651	48
1953	831	65
1954	560	32
1955	448	29
1956	689	43
1957	1167	83

Prevention and Cure in Sweden

In a talk broadcast on April 11, Miss Joan Lamont described Sweden as an example and an inspiration to the public-health worker The infant death rate, she said, was half that in Scotland, and the expectation of life greater, tuberculosis, thanks partly to B C G vaccination, had " almost vanished "

She found that the differences were due to neither a better climate nor a higher standard of living, but rather to the emphasis on prevention in the training of nurses and doctors, and to the allocation of adequate money to preventive services, although expenditure on all health services was less than in Britain For equal numbers of people there were fewer consultants, general practitioners, and hospital nurses in Sweden than in Britain, but many more public-health doctors and nurses There were enough of these nurses (the equivalent of our health visitors) to do all the important jobs that needed them Student nurses were treated as students, and were not used for routine ward-work any more than were medical students in Britain The student spent a fair proportion of her nursing training with public-health nurses, and, even if she remained in hospital work, kept her interest in teaching health and preventing disease Ward-orderlies were employed to do the unskilled work, and the prestige of nursing was such that it got its fair share of recruits of high calibre

The Swedes, said Miss Lamont, had discovered that " prevention pays dividends not only in money but also in human happiness "

[3] *Manchester Guardian*, June 22 1957

The tuberculin courses given by Smith and Vollum [1, 5] in meningitis and by Howells and Swithinbank [2] in pulmonary tuberculosis were designed specifically to provoke as many focal reactions as possible before the development of desensitisation For this reason injections of tuberculin were spaced at intervals of 5 or 7 days These series were not designed to study the significance of prolonged desensitisation and in neither instance was there any plan to continue tuberculin therapy as a long-term outpatient measure The detailed daily C S F examinations which are an essential part of Smith and Vollum's routine give a quantitative picture of the focal reaction in the tuberculous theca In pulmonary tuberculosis the focal reaction can only be presumed from the presence of a mild general reaction characterised by fever, malaise, and, in some cases, brief increase in local symptoms and signs These reactions, it is true, cause the patient some inconvenience Not one of my 78 patients has asked to discontinue the course on account of unpleasant reactions In one of the Oxford cases, tuberculin reactions provoked hæmoptysis from a giant cavity, and the treatment had to be stopped for this reason

The focal tuberculin reaction is, as you say, a hyperæmic phenomenon designed to carry the antimicrobial drugs to the place where they will do the most good It must be emphasised, however, that it is the inaccessible and not the resistant bacillus at which the reactions are aimed There is little, sense and there may be real danger, in provoking hyperæmia in tuberculous tissues if the bacilli are thereby exposed only to drugs to which they are resistant

Oxford

F RIDEHALGH

PRIMARY HEPATIC CARCINOMA

SIR,—Your annotation of April 6 draws certain conclusions which do not appear altogether justified While it is true that primary carcinoma of the liver is common in oriental countries and parts of Africa, there is insufficient evidence to justify the conclusion that the incidence is highest among the Bantu Negro The older reports from this Institute refer to highly selected groups of young adult males in whom liver cancer is the most common tumour While there is some evidence that the Bantu tribes in Portuguese East Africa may have a much higher incidence than those of the Union of South Africa,[6] comparison with the West African Negro is as yet impossible in the absence of incidence studies, which are only now being initiated Visits to Uganda, the Belgian Congo, and French West Africa, however, have given me the impression that carcinoma of the liver is at least as common if not more frequent in some of these areas than in South Africa and what statistics are available support this view [7]

In a series of necropsies from a general Bantu hospital in Johannesburg, primary carcinoma of the liver constituted slightly more than 2% of all necropsies In a rate study, we found, however, that the incidence of primary carcinoma was 22% of all carcinomas in males [8] While this relatively high frequency is mainly due to a high absolute incidence, it is accentuated by the composition of the population at risk which includes a high proportion of young adult males The reduced incidence of cancer of the skin and of the gastro intestinal tract in the local African also increases the relative frequency

It is difficult to compare the frequency of cirrhosis in different populations, since we are dependent chiefly on post mortem studies In the United States the frequency of cirrhosis usually varies between 2 and 5% of all necropsies,[9] whereas the frequency of cirrhosis at post mortem in Johannesburg in the Bantu is approximately 9 1% in males and 4 0% in females [10] On the other hand, for 1947–54, at the Boston City Hospital, in the series quoted by your editorial, the frequency was 13 93% [11] While this hospital may not be representative of the United States as a whole, it is probably similar to those hospitals serving the Bantu population of South Africa These observations should cast some doubt on the statement that the high incidence of primary liver cancer in Africa is mainly attributable to a higher frequency of cirrhosis There is evidence on the other hand, however, to suggest that the high incidence of liver cancer in the African Negro and in other countries with a high incidence, may be dependent on the high frequency with which cirrhosis undergoes malignant change [12] Approximately 54% of cirrhotic livers in males at post mortem in Johannesburg show malignant change

You also state that the relationship of dietary deficiency to cirrhosis in both man and laboratory animals is now well established While this may be true for animals, the rôle of nutrition in liver disease in man is far from clear The only relatively well documented, "nutritional" liver disease in man is the fatty liver of kwashiorkor, in which cirrhosis is a very rare sequel

In European practice the term "nutritional cirrhosis" is applied to the common "alcoholic" or Laennec's cirrhosis although the nutritional ætiology is by no means universally accepted Livers of this nature, although common among the white races of South Africa, are exceedingly rare in the indigenous and poorer Bantu population [10] In contrast the common cirrhosis in which carcinoma develops in South Africa is not of this type, but usually has the features of a post necrotic or post hepatitic cirrhosis The ætiology is definitely unknown, but according to French studies, this cirrhosis may be viral in origin [13] and our experience supports this view Nutrition as a direct factor in this type of cirrhosis has not been demonstrated

I would therefore like to suggest that (i) a high frequency of cirrhosis has not yet been shown to be the cause of the high incidence of liver cancer in under privileged communities, (ii) the relationship of diet to liver cancer and cirrhosis is by no means satisfactorily proven, and (iii) that the term "nutritional cirrhosis" in man be dropped until it can be used with greater knowledge of the ætiological background

Medical Research,
Johannesburg

JOHN HIGGINSON

THE WORD "ISOTOPE"

SIR,—This word, now so familiar, was introduced in Glasgow about 1912 by a medical woman—Margaret Todd, who was also a novelist writing under the name Graham Travers—to fit the concept of elements occupying the same place in the periodic table The occasion was a social gathering at 11, University Gardens, then the home of Sir George Beilby (the father-in law of the late Frederick Soddy, who originated the concept of isotopes and other achievements in radiochemistry including the first approach to atomic numbers) Having been obliged to use awkward periphrases to express his "isotopic" ideas, Soddy said he needed a word for the concept, Dr Todd immediately suggested *isotope—iso*, the same, *topos*, place The word had indeed been published a few years before in a context of organic chemistry, but there is no reason to suppose that Dr Todd was aware of that

Notes and News

NATIONAL ASSISTANCE BOARD

THE report[1] of the board for 1956, shows that the number of weekly allowances rose during the year by 44,000 to 1,656,000 (covering the needs of over 2¹/₄ million people) Payments of assistance in 1956 amounted to £105,160,000 More than two thirds of the allowances went to supplement national insurance benefits, including 117,000 to supplement sickness benefit or industrial injury payments

About 300,000 people were registered as unemployed in December of last year Of these, 73,000 were receiving assistance allowances (compared with 61,000 a year before) During 1956 the board collected information about people whose assistance was paid only on condition that they registered for employment The results show that the hard core of the unemployed maintained by national assistance consist mainly of disabled persons and unskilled men and women with physical or mental limitations which restrict their chances of getting and keeping a job During the year the number of reception centres for people without a settled way of living fell from 109 to 68 The average nightly number of people using the centres was about 1800, 130 more than in 1955

URINE TEST FOR PHENYLKETONURIA

A SIMPLE test, using ferric chloride, has been devised for the detection of phenylpyruvic oligophrenia, and it has been recommended that every child be tested at the age of 21 days If it is positive, dietary treatment can be started at once Cards describing and illustrating the test may be had from the Secretary, The Hospital for Sick Children, Great Ormond Street, London, W C 1, at 6*d*

University of Cambridge

Dr P J Randle has been elected to an official fellowship at Trinity Hall

On June 15 the following degrees were conferred

M.D —Gordon Scott
M B, *B Chir* —J M L Goddard (by proxy), R C M Kew
M.B —P J Lachmann

University of London

Sir John Charles has been appointed Heath Clark lecturer for 1959

Mr G H Bourne, D SC, is resigning the readership in histology at London Hospital Medical College on Sept 30, to take up the appointment of professor of anatomy and chairman of the anatomy department of Emory University, Georgia

University of Sheffield

Dr G R Hervey has been appointed lecturer in physiology

University of Glasgow

On June 19 the honorary degree of LL D was conferred on Sir James Paterson Ross and Brigadier J S K Boyd, F R S

Royal Society of Tropical Medicine and Hygiene

Brigadier J S K Boyd, F R S, has been elected president for the coming two years

Society of Medical Officers of Health

Dr H D Chalke has been elected president, and Dr C Metcalfe Brown chairman of council, of this society for 1957–58

World Federation of Societies of Anæsthesiologists

The World Congress of Anæsthesiologists is to be held in Toronto from Sept 4 to 10, 1960 All inquiries should be addressed to Dr R A Gordon, chairman of the organising committee, 516, Medical Arts Building, Toronto 5, Ontario

National Association for the Prevention of Tuberculosis

This association will commemorate the centenary of the birth of Sir Robert Philip by placing a tablet on the wall of 13, Bank Street, Edinburgh, where he founded the first tuberculosis dispensary in 1887 Mr Walter Elliot will unveil the plaque on Friday, July 26, after a short ceremony to be held at noon in court room no 4, Sheriff Court House, High Street, Edinburgh

World Congress of Gastroenterology

This congress will be held in Washington, D C, fr May 25 to 31, 1958 Further particulars may be had fr Dr H M Pollard, University Hospital, Ann Arbor, Michig U S A

Royal Medico-Psychological Association

The annual meeting of this association will be held Oxford from July 2 to 5 under the presidency of Dr R Armstrong Further particulars may be had from t secretary of the association, 11, Chandos Street, London, W

Christian Medical Fellowship

This fellowship will hold its annual breakfast on Tuesda July 16, at 8 15 A M, at the Royal Station Hotel, Newcas upon Tyne Mr Weldon Watts will be in the chair a Dr R G Cochrane will speak on Changing Standards Medical Practice Further particulars will be found in o advertisement columns

International Congress of Internal Medicine

The International Society of Internal Medicine is to hold fifth congress next year from April 24 to 26 in Philadelph under the presidency of Dr T Grier Miller This will be t first time that the society has met outside Europe T secretary general is Dr E R Loveland, 4200, Pine Stree Philadelphia, Pa

Psychiatric Congresses at Zurich

The International Congress of Group Psychiatry is to b held at Zurich from Aug 29 to 31 The following day, Sept the International Congress of Psychiatry will begin, and th will continue till Sept 7 Its main theme is the Presen Status of our Knowledge about the Group of Schizophrenia Further particulars about both congresses may be had fro the secretariat, Lengstrasse 28, Zurich 8, Switzerland

Harveian Society of London

The summer meeting of this society was held on Sunda June 23, when more than 60 members and guests attended service at Hempstead Parish Church, Essex, where Harve is buried Dr R Cove Smith gave an address and the servic ended with prayers of thanksgiving and re dedication by th Bishop of Colchester Afterwards Mr Dickson Wright wa presented with a gold medallion to mark his presidency of th society and of the Harvey tercentenary congress

Wellcome Trust

The Wellcome Trustees have made a grant of £5000 t McGill University, Montreal, for the purchase in the sterlin area of books related to the history of medicine which ar needed to fill gaps in the Osler Library The Trustees hav also agreed to provide £1200 annually for twenty five year to assist the further development of this library A ne extension and reading room for the library, to be known a the Wellcome Camera is to be provided by the university

The Brain and its Functions

An Anglo American symposium on the history and philo sophy of knowledge of the brain and its functions is to be hel in London from July 15 to 17 in connection with the first International Congress of Neurological Sciences, which is t take place in Brussels from July 21 to 28 The symposium i sponsored by the Wellcome Historical Medical Library with the cooperation of the National Hospital, Queen Square, and the Maudsley Hospital Further particulars may be had from Dr F N L Poynter at the library, Euston Road, N W 1

Reorganisation of Local Government

At a meeting of the Rural District Councils Association (*Times*, June 20) Mr Henry Brooke, Minister of Housing and Local Government, said that he hoped that a Bill on local government reorganisation would be ready in the autumn He realised that some of the smaller councils were disappointed because the white paper did not offer them much in the way of additional functions, but he thought that we must face realities Today some of the larger services, such as health and education, could not be operated over small units But the Government proposed that the larger urban authorities—those with a population of at least 60,000—should automatically be given charge of the local health and welfare services which at present were exclusively a county council responsibility He believed that this would be a big step in the right direction for a service in which "the personal element matters so much, and to which the local elected representative has a personal contribution to make"
